P. Fe

THE ENGINEERING RECORD

ESTABLISHED 1877

BUILDING RECORD AND THE SANITARY ENGINEER

CONDUCTED BY HENRY C. MEYER.

VOLUME XLVI.

106836
20.12.10

JULY–DECEMBER, 1902.

114 LIBERTY STREET,
NEW YORK.

INDEX

JULY—DECEMBER, 1902.

The abbreviation (†) signifies illustrated articles.

GENERAL.

A

Accidents:
  Blasting Niagara Falls, 517.
  Break in a cast-iron pipe Thirlmere aqueduct, 511.
Accounting:
  Property returns on public works, 608.
Air:
  Apparatus for liquefying, Cornell University, 296.
Air, Compressed:
  Economy derived from reheating, 221 †.
  Use in Buffalo grain elevator, 131 †.
Aldershot, Eng.: Recent municipal work, 618.
Alternators:
  Parallel running engine governing, 275.
Altoona, Pa.:
  Septic tanks, 584.
Aluminum:
  Reduction of alumina in America, 440.
  Wire joints, 515.
American Institute of Architects, Convention, 577.
American Society of Civil Engineers, Dishonest use of name, 607.
American Society of Mechanical Engineers, Meeting, 545, 553.
American Society of Municipal Improvements, Meeting, 353.
American Water Works Association:
  Letter from a member, 40.
Amsterdam, N. Y.:
  Dam and reservoir, 602 †.
Aqueducts:
  Break in Thirlmere, Manchester, Eng., 511.
  Loss of capacity, the Vyrnwy, Liverpool, Eng., 103.
  Weston, Boston water works, 362 †, 386 †.
Arad, Hungary:
  An unusual water supply plant, 296.
Architecture:
  Contest for Greek church, 522.
  Ensemble effect of buildings, 497.
Arches:
  Blackwell's Island bridge masonry, 554 †.
  Heavy concrete in Peoria & Western R. R. bridge, 199 †.
  Reconstruction culverts, Grand Rapids, Mich., 444.
  Rock Creek concrete-steel arch, Washington, D. C., 151 †.
  Steel, Pennsylvania trainshed, Pittsburg, 172 †.
  Two-hinged, 603 †.
Ash carts:
  New type used in New York City, 269.
Asphalt:
  Coating of steel main, New Bedford, Mass., 57.
  For bridge flooring, 426.
  In sewer pipe joints, Berlin, 1.
  Paving in New York City, 281.
  Plant for the manufacture of, at Winnipeg, Man., 32.
Association of Municipal Engineers of New York City, 447.
Atlantic City, N. J.:
  30-inch riveted steel force main, protected with mineral rubber, 89.
Attleborough, Mass.:
  Iron in water supply, 614.
Automobiles:
  Use in France, 426.

B

Bacteria:
  Treatment of trade wastes, 273.
  Stability of effluents from sewage filters, 611.
  Vitality of sewage, and antagonism of soil bacteria to typhoid bacillus, 440.
Base line measurements:
  Rapid methods, 98th meridian triangulation, 293 †.
Baths:
  Report of Sewerage and Sanitation Committee, Am. Soc. Mun. Imp., 372.
  Swimming, Ansonia Hotel, New York, 543 †.
  Use of public, Chicago, 535.
  Yonkers, N. Y., public use of, 610.
Beams:
  Reinforced concrete, 1.
Bedford, Ind.:
  Septic tank, 465 †.
Bench marks:
  Chicago standards, 592.
  Hartford, Conn., 490 †.
Berlin, Germany:
  Smoke abatement, 399.
  Stoppage of sewers by tree roots, 1.
Birmingham, Eng.: Septic tank sewage disposal, 16.
  Roadways, 610.
Blasting:
  Accident at Niagara Falls, 517.
  Blackwell's Island bridge construction, 554 †.
Blueprints:
  Machine for wringing, 12.
Boats:
  Motion of, in a restricted water-way, 40.
Boilers, Steam:
  British admiralty report of, 149.
  Cold heating of rivets for, 231.
  Hohenstein water-tube, 586 †.
  Manufacture in shops of Babcock & Wilcox Co., 529 †.
  Scotch marine type in office building, 86 †.
  Sederholm, 584.
Book notes (See New Publications).
Boston, Mass.:
  Cost of pumping water, 151.
  Prevention of water waste, 245.
  Sewage reservoir, electro-pneumatic control of, Moon Island, 181.
  Underground railway project, 607.
  Weston aqueduct, 362 †, 386 †.
  Water consumption, 618.
Breakwaters:
  Concrete blocks in Buffalo, 400.
Bricks:
  Plant for paving bricks, 462 †.
Bridges:
  American shop practice in, 97.
  Bascule, Grand Ave., Milwaukee, Wis., 38 †.
  Blackwell's Island bridge superstructure, New York, 580.
  Burr bridge, Harrisburg, Pa., 249.
  Concrete-steel arch, Rock Creek, Washington, D. C., 151 †.
  Cooper specifications for foundations, 414 †.
  Double deck railway, Pittsburg, 338 †, 364 †.
  Eighteen Mile Creek viaduct, 266 †.
  Foot suspension bridge, Easton, Pa., 129 †.
  Glendive, Montana, highway, 161.
  Heavy concrete arch, Peoria & Eastern R. R., 199 †.
  High level bridge, Newcastle-on-Tyne, Eng., 303 †.
  Kew, over Thames, construction of, 522.
  Long bridge in India, 57.
  Manhattan, New York, tower foundations, 510.
  Max Joseph, Munich, 324 †.
  Moving a railroad bridge, New Brunswick, N. J., 10 †.
  New East River, New York,
    Cables of, 400.
    Fire, 457, 458 †, 464, 492.
    Resumption of work, 587.
  Partial failure of concrete piers at Joliet, Ill., 55.
  Pennsylvania R. R., 52d St., Philadelphia, 398 †.
  Pier and pavilion, Bar Harbor, Me., 424 †.
  Plate girder, Lake Erie & Western R. R., 152 †.
  Reconstruction, Redheugh, Eng., 134.
  Recovery of steel from Des Moines River, 426.
  Removal So. 10th St., Pittsburg, 521.
  Rio Grande, Costa Rica, 390 †, 434 †, 515, 613.
  Rolling bridge, Westchester Ave., New York, 79 †.
  Single grade of steel for, 49.
  Sudbury River pipe arch, Weston aqueduct, 386 †.
  Toll bridge, St. Charles, Mo., 34.
  Two-hinged arch, 603 †.
  Uganda Railway, erection, 105 †.
Bridge erections:
  (See Contractor's plants.)
Bridge piers:
  Blackwell's Island, New York, 554 (†).
  Cooper's specifications, 414 (†).
Bristol, England:
  Provision for redistributing coal in the bunkers, 29.
Brockton, Mass.:
  Intermittent plant for sewage disposal, 161.
Brooklyn, N. Y.:
  Electrolysis in Navy Yard, 181.
  Fire insurance rates, 583.
  Large sewer tunnel, 226.
  Result of a study of water distribution, 330.
  Sanitary protection, 565.
  Slippery pavements, 301.
Buildings:
  Bank of the State of New York;
    Superstructure, 242 (†).
    Underpinning, 299 (†), 417 (†).
  Battery Place building, New York, 59 (†).
  Blair building, New York, 227 (†).
  Cellar bracing, New York Stock Exchange, 155 (†).
  Chamber of Commerce, New York, dedication, 466.
  Columns for, 457.
  Complicated underpinning, Bank of the State of New York, 299 (†), 417.
  Corrosion of steel frames, 442 (†).
  Fore River shipbuilding shed, Quincy, Mass., 85 (†).
  Government Printing Office, 535 (†).
  Hibernia, New Orleans, 486 (†), 506 (†).
  North German Lloyd pier sheds, Hoboken, N. J., 8 (†), 58.
  Pantheon, 277 (†).
  Pennsylvania trainshed, Pittsburg, 172 (†); erection, 419 (†).
  Philadelphia Co., Pittsburg, 320 (†).
  Proposal of a single grade of steel, 49.
  Replacing stone front, New York, 135 (†).
  Rhode Island Suburban Ry. repair shops, Providence, 107 (†).
  Sangley Point coaling plant, Manila, 123 (†).
  Steel pier and pavilion, Bar Harbor, Me., 424 (†).
  Underpinning Decker Building, New York, 11 (†).
  Water tower, Grand Rapids, Wis., 441 (†).
  Westinghouse foundry, 324 (†).
Bury, Eng.:
  Sewage disposal works, 32.

C

Cables:
  British-Pacific completion, 464.
  New East River Bridge, New York, 400.
Cableways:
  Deep Gulch, Col., 76.
Calcutta, India:
  Dual water supply, 126.
Caissons:
  Cooper's bridge foundation specifications 414 (†).
Camden, N. J.:
  Break in reservoir, 343 (†).
Canals:
  Another Isthmian route (LeBaron), 505
  Boat motion in a restricted waterway 40.
  Chicago's drainage litigation, 416.
  Earnings of Manchester Ship Canal Co. 275.
  Lake Ontario route for barge (N. Y State), 601.
  Panama Canal Co.'s title, 413.
  Panama route, 1.
  St. Lawrence County, N. Y., 247.
  Suez transit dues, 535.
  Surveys for, in Central America, 57.
Canton, O.:
  Legal decision as to rights to river water, 132.
Cement:
  Chemical analysis of Portland, 129.
  Exhibits, Düsseldorf Exhibition, 341.
  Grouting subaqueous walls, 585 (†).
  Output for 1901, 11.
  Output for five years, 399.
  Protection of steel, 442 (†).
  Retempering mortar, 615.
  Standard specifications, 25.
  Standard specifications (R. W. Lesley), 4.
  Testing in Municipal laboratories (R. L. Humphrey), 27.
  Tests of, for New York Rapid Transit Co., 505.
  Use of slag, 416.
Cement plants:
  Pacific Portland Co.'s Works, Suisun, Cal., 201 (†).
  Two English, 184.
Census:
  Peculiarities of industries, 409.
Central States Water-Works Association, Convention, 323.
Charleston, S. C.:
  Distribution of disinfectants, 464.
  Sanitary inspection, 494.
Chicago, Ill.:
  Concrete sewer construction in, 104.
  Garbage removal, 594.
  Pumpage of water, 610.
  Standard bench monuments, 592.
  Street cleaning ordinance, 558 (†).
  Water-waste, 569.
Chimneys:
  Berlin, Ger., plant, with rooms in base, 465.
  Refrigerating plant, Manila, P. I., 2 (†).
  Stability of high, 495.
  Stability of, Prussian regulations, 60.
China:
  Duties on imports into, 522.
Chino, Cal.: Oiled roads, 373.
Cienfuegos, Cuba:
  Water-works and sewers contract, 497.
Clayton, Mo.: Septic sewage, disposal for county court building, 247.
Cleveland, O.:
  Water-works tunnel progress, 588.
Clinton, Mass.:
  Intermittent sewage filtration plant, 160.
  Leaky sewer, 258.
Coal:
  Early anthracite, 385.
  Economy of use in power production, 491.
  Electric mining in England, 413 (†).
  Rowe system of burning pulverized, 592 (†).
  Siberian production, 560.
  World's production, 399.
Coal bunkers:
  In Sangley Point coaling station, Manilla, 123 (†).
Coal handling machinery:
  Means of retrimming coal, Bristol, Eng., 27.
  Prudential Buildings, Newark, 367 (†).

Sangley Point coaling plant, Manila, 123 (†).
Coal mines:
Electrical apparatus in English, 413 (†).
Cofferdams:
Repairing leaks, Massena, N. Y., 176.
Coke ovens:
By-product, Growth of, 328.
Lackawanna Iron & Steel Co., 11.
Columns:
Bank of the State of New York, 242 (†).
Blair building, New York, 227 (†).
For buildings, 457.
Use of a sand box under (500 B. C.), 218.
Concrete:
Blocks in Buffalo breakwater, 400.
Compressive resistance of hooped, Considere, 581, 605.
Corrosion of steel frames in buildings, 442 (†).
Culvert for Western & Atlantic R. R., 82.
Exhibits, Düsseldorf Exhibition, 341.
Expansion of (C. A. Lyford), 226.
Experiments with wet, medium and dry, 301.
Failure of a retaining wall, Sea Girt, N. J., 36.
Fire test of lock woven metal floor, 350 (†).
Heavy arch bridge, Peoria & Western, R. R., 199 (†).
Modulus of rupture, 615.
Partial failure of bridge piers, Joliet, Ill., 55.
Sewer construction in Chicago, 104.
Sewers, Truro, Nova Scotia, 196 (†).
Sidewalks, Toronto, 619.
Tunnels for pipe subways, University of Nebraska, 62.
Unreasonable Government specifications, 265, 289, 313.
Weston aqueduct work, Boston, 362 (†), 386 (†).
Concrete-steel construction:
Bridge over Rock Creek, Wash., D. C., 151 (†).
Columns for buildings, 457.
Compressive resistance (Considere), 581, 605.
Durability of, 337.
Durability of steel in, 280.
Expanded metal, concrete slab, 106 (†).
Harrisburg sewers, 341 (†).
Loading test Ransome floor, 580 (†).
Paper by Prof. Brik, 177 (†).
Piers for Bascule bridge, Milwaukee, Wis., 38 (†).
Piles, 560.
Piles, Hennebique system, 618 (†).
Reinforced concrete beams, 1.
Reservoir, Newton, Mass., 197 (†).
Strength of (Considere), 320.
Tests of White and American floors, 421 (†).
Theory and computations, 241.
Condensers:
Air cooled, type, Ansonia hotel, New York, 467 (†).
Manchester school experimental, 472 (†).
Construction methods:
(See Contractor's plants.)
Contracts:
General and separate, 385.
Limited franchises, 601.
Made for city engineer for work in Toronto, 397.
Separate versus general, 386.
Troubles with (J. C. Wait), 179.
Unreasonable requirements by the Government, 265, 289, 303, 313.
Contractor's plants:
Battery Place building, New York, 59 (†).
Blackwell's Island bridge, masonry construction, 554 (†).
Blair building, New York, 227 (†).
Cellar bracing, New York Stock Exchange building, 155 (†).
Complicated underpinning, Bank of the State of New York, 299 (†).
Concrete sewer construction, Chicago, 104.
Concrete sewer, Truro, Nova Scotia, 196 (†).
Erection P. R. R. trainshed, Pittsburg, 419 (†).
Erection of Uganda Railway bridge, 105 (†).
Erection of viaduct, N. Y., Chic. & St. L. Ry., 266 (†).
Excavation for Wachusett reservoir, Boston, 161.
Fore River shipbuilding shed, Quincy, Mass., 85 (†).
Foundation laying, Bank of State of New York, 242 (†).
Grouting subaqueous walls, 585 (†).
Highway bridge, Glendive, Mont., 161.
Kew bridge, England, 522.
Lauchensee dam, Alsace-Lorraine, 193 (†).
Lowering foundation girder, New York city, 205 (†).
Method of building a long bridge in India, 57.
Moving a railroad bridge, New Brunswick, N. J., 10 (†).
New Croton dam, New York, 146 (†).
North German Lloyd piersheds, Hoboken, N. J., 8 (†), 58.
Pike's Peak Power Co.'s plant, 50 (†).
Reconstruction Castlewood dam, 34 (†).
Reconstruction of Lake Winnibigoshish dam, 250 (†).
Reconstruction of Redheugh bridge, 134.
Removal of a Pittsburg bridge, 521.
Repairing leaky cofferdams, 176.
Repairs on a railroad bridge at Joliet, Ill., 55.
Replacing stone front of building, New York, 135 (†).
Rio Grande, Costa Rica, bridge, 390 (†), 434 (†), 515.
Second division N. Y. Rapid Transit R. R., 52 (†), 81 (†), 102 (†).
Sinking iron pile, Hoboken, N. J., 200.
Submerged pipe laying, Jersey City water-works, 558 (†).
Underpinning for Bank of State of New York, 417 (†).
Underpinning a brick building, New York, 11 (†).
Water well sinking, Kalamazoo, 148 (†).
Weston aqueduct, Boston water-works, 362 (†), 386 (†).
Conveying machinery:
Pacific Portland Cement Co.'s Works, Suisun, Cal., 201 (†).
Cost accounting:
Of work in progress, 271.
Crematories:
Garbage, Investigation of (R. Hering), 253.
Garbage, Winnipeg, Man., 161.
Crenothrix:
Rust stains from water containing it, 75.
Culverts:
Austrian highway, 347 (†).
Concrete for Western & Atlantic R. R., 82.
Reconstruction, Grand Rapids, Mich., 444.
Weston aqueduct, Boston water-works, 362 (†), 386 (†).

D

Dams:
American, Failures of (W. R. Hill), 290 (†).
Amsterdam, N. Y., reservoir, 602 (†).
Assuan, Egypt, completion, 145, 553.
Circular, Lake Cochituate, 497 (†).
Concrete, Middle Falls, N. Y., 318 (†).
Concrete, near London, Ontario, 78 (†).
Croton, New York, 146 (†).
Shortening working day, 494.
Development in design and construction of high, 121.
Diversion, for submerged pipes, Jersey City, 558 (†).
High concrete, McCloud River, 433.
Impermeable masonry, 169.
Lauchensee, Alsace-Lorraine, 193 (†).
Muscoot, Croton Valley, New York, 578 (†).
New London, Conn., reservoir, 482 (†).
Pike's Peak Power Co.'s plant, 50 (†).
Reconstruction, Lake Winnibigoshish, 250 (†).
Reconstruction of Castlewood dam, near Denver, Col., 34 (†).
Reconstruction of stone, 401 (†).
Repairing a leaky cofferdam, 176.
Timber, Life of, 401.
Wachusett,
Progress on, 413.
Tests of cement mortar, 150.
Dampers:
Size of, for mechanical draft work, 314.
Danville, Ky.:
Septic tanks, 537.
Degrees:
Doctor of Engineering, Mass. Inst. Tech., 563.
Derricks:
Blackwell's Island bridge construction, 554 (†).
Detroit, Mich.:
Anchor ice in water-works intake, 437.
Efficiency of water-meters, 450.
Dictionaries:
Technolexicon (Eng., Ger., Fr.), 229.
Disinfection:
At Charleston, S. C., 464.
Docks:
North German Lloyd piersheds, Hoboken, N. J., 8 (†), 58.
Domes:
The architecture of the Pantheon, 277 (†).
Drafting:
Illuminated tracing table, 395.
System in a British engine shop, 63.
Universal sketching device, 520 (†).
Draftsmen:
Salaries of New York topographical, 481.
Drainage:
Minnesota Commission work, 1.
Sewerage and Sanitation Committee, Am. Soc. Mun. Imp., 372.
Storm water run-off, Philadelphia, 465.
Drainage in buildings:
Carnegie residence, 108 (†).
Flat-iron, New York, 326 (†).
Inspection, Charleston, S. C., 494.
Drawings:
Sketching device for, 520 (†).
System of drafting in a British engine shop, 63.
Title printing Philadelphia Bureau of Filtration, 569.
Dredges:
Hydraulic, on St. Lawrence River, 75.
Hydraulic, for St. Louis settling basins, 439.
Dredging:
Cost of, with different plants (J. Bogart), 247.
Galveston, Tex., 371.
Dry docks:
Charleston, Unreasonable contract requirements, 265, 289, 303, 313.
Dryers:
Cummer self-contained, 377 (†).
Duties:
Imports into China, 522.
Dynamo:
Testing (E. H. Rayner), 225.

E

Economizers:
Cambridge Elec. Lt. station, 410 (†).
Education:
American School of Correspondence and Armour Institute arrangement, 200.
Economic need of technical, 111.
Prof. Perry on technical, 337, 487.
Specialization in engineering, 73.
Electricity:
Influence of capacity in electric transmission, 298.
Prices paid in Riverside, Cal., 412.
Single-phase alternating-current railway operation, 269, 389.
Stray currents, Worcester, Mass., 326.
Electric plants:
Aldershot, Eng., 617.
Bay Counties Power Co., 298.
C. & C. Shaft, Virginia City, Nev., 171 (†).
Cambridge Elec. Light, 410 (†).
Edison Electric Co., Los Angeles, Cal., 151.
English coal mines, 413 (†).
Grain elevator, Buffalo, 131 (†).
Pole construction, Pacific slope, 317.
Puyallup River, Wash., 498.
Regulation in two Arve River water-power plants, France, 150.
Utilization of waste gases, Union Steel Co., 298.
(See Power plants, etc.)
Electric railways:
(See Traction and Railways.)
Electrolysis:
Iron pipes in Boston, 147.
Stray current in Worcester, 326.
Water mains, Cob Dock, Brooklyn Navy Yard, 181.
Elevators:
Plunger type, Ansonia apartment hotel, 467 (†).
Sprague electric, 132 (†).
Elevators, Grain:
Power equipment of a Buffalo, 131 (†).
Embankments:
Break of Camden reservoir, 343 (†).
Engineering:
A new departure in consulting, 241.
Compensation for, 361.
Degree of doctor of, Mass. Inst. Tech., 563.
Economic need of education in, 111.
John Fritz medal, 433.
Mathematics in education (Perry), 337, 487.
Patents and ethics, 193.
Progress in civil, 145.
Progress in sanitary, 302.
Specialization in the education in, 73.
Engineering Record, change of ownership, 457.
Engineers:
Advice to young, 481.
Association of New York City Municipal, 447.
Compensation of, 361.
Government requirements for civil, 185.
Question of patenting inventions, 193.
Salaries of New York subordinate, 481.
Escalators: In department store, New York, 449 (†).
Excavations:
Earth, Sewerage and Sanitation Com., Am. Soc. Mun. Imp., 372.
For Wachusett reservoir, Boston, 161.
Second division N. Y. Rapid Transit R. R., 52 (†), 81 (†), 102 (†).
Simplon tunnel, Eng., 279.
Weston aqueduct, Boston, 362 (†), 386 (†).
Exeter, Eng.: Extension of septic tank system, 258.
Expanded metal:
In concrete slab, test of (O. W. Connet), 106 (†).
Harrisburg concrete sewers, 341 (†).
Swimming bath, Ansonia hotel, New York, 543 (†).
(See Concrete-steel construction.)

F

Fans:
Proportions of centrifugal, 349 (†).
Field Engineering: (See Contractor's plant.)
Filtration, Sewage:
Brockton, Mass., intermittent, 161.
Clinton, Mass., intermittent, 160.
Nuneaton, Eng., 328.
Operation of plants (Alvord), 537 (†).
Stability of effluents with filters of coarse materials, 611.
Stoddart continuous, 174 (†).
Filtration, Water:
Calcutta water supply, 126.
Maignen preliminary for sand filtration, 76 (†), 484.
Method of regulating mechanical (Central States W-W. Asso.), 323.
Scrubbers for (Am. Water-Works Asso.), 76 (†).
Springfield, Mass., experiments, 614.
Fireproofing:
Government Printing Office, 535 (†).
Fire protection:
Automatic sprinklers (Central States W-W. Asso.), 323.
Fire streams (Central States W-W. Asso.), 323.
Tests of uralite, 584.
Fires:
East River Bridge, New York, 457, 458 (†), 464, 492.
International Fire Exhibition, London, 522.
Losses by forest, 419.
Floors:
Concrete-steel, 177 (†).
Fire test of lock-woven metal concrete, 350 (†).
Government Printing Office, 535 (†).
Tests of American and White floor systems, 421 (†).
Test of Ransome concrete-steel, 580 (†).
Wearing surface of bridge, 426.
Forestry:
Losses by fires, 419.
Map of Appalachian reserve, 569.
Preservation of Russian, 588.
San Jose scale, 579.
Foundations:
Bank of the State of New York, 242 (†).
Blair building, New York, 227 (†).
Cooper's specifications for bridges, 414 (†).
Grouting subaqueous walls, 585 (†).
Hibernia building, New Orleans, 486 (†).
North German Lloyd piersheds, Hoboken, N. J., 8 (†), 58.
Philadelphia building, Pittsburg, 320 (†).
Tower, Manhattan Bridge, New York, 510.
Underpinning for Bank State of N. Y., 417 (†).
Foundries:
Westinghouse, Trafford, Pa., 324 (†).
Franchises:
Limited, 601.
Fritz medal, John, 433.
Fuel:
Liquid fuel, burning, without steam jet, 84.
Peat fuel in Stangfiorden, Norway, 29.

G

Gallipolis, Ohio, Water Supply, 34.
Galveston, Tex.: Oiled shell roads, 378.
Garbage disposal:
Chicago, 594.
Crematory, Winnipeg, 161.
Investigation of a crematory for, 253.
Gas:
Utilization of blast furnace, 298.
Gas engines:
Entropy analysis of Otto Cycle (Am. Soc. M. E.), 553.
Faulty ignition, 619.
Large, 121.
Selection of (J. D. Lyon), 283.
Several installations in industrial plants, 512.
Girders:
Lowering a heavy one for a New York office building, 205 (†).
Glass:
Diffusion of light through, 448.
Glen View, Ill.: Sewage purification, 537.
Governors: For engines in the parallel running of alternators, 275.
Grand Rapids, Mich.:
Arched culvert reconstruction, 444.
Brick pavements, 520.
Gravel roads, 366.
Permits for opening streets, 440.
Portland cement pavements, 397.
Sewer enlargement, 466.
Water-meter experience, 351.
Grand Rapids, Wis.:
Water tower, 441 (†).

Street cleaning:
Chicago ordinance, 558.
Disinfection, Charleston, S. C., 464.
Hand sweeping machines, Washington, 326.
International committee on street hygiene, 367.
Patrol system, Somerville, Mass., 40.
Snow removal, New York, 464, 563.
Street railways:
(See Railways and Tractions.)
Street sprinkling:
Meters for wagons (Central States W-W. Asso.), 323.
Subways:
Boston and New York undertakings, 583.
New York Rapid Transit:
Review of work, 505.
Second division, 52 (†), 81 (†), 102 (†).
Pipe, University of Nebraska, 62.
Washington St., Boston, lease, 395.
Surveying:
For ship canal routes in Central America, 57.
Measurement of 98th meridian base lines, 293 (†).
New York State maps, 589.
Standard bench monuments in Chicago, 592.
Swamps:
Reclamation in Minnesota, 1.
Syphons:
Harrisburg sewer system, 341 (†).
Use in the classification of water supply, St. Louis, Mo., 32 (†).
Weston aqueduct, Boston water-works, 386 (†).

T

Tanks:
North German Lloyd experimental, 512.
Water storage, Assabett Mills, 314 (†).
Tar:
On French roads, 587.
Telegraph:
British Pacific cable competition, 464.
Tests:
Apparatus for collecting water at various depths, 137 (†).
Bulkhead for pipe, Jersey City, 558 (†).
Cement testing in municipal laboratories (Humphrey), 27.
Engine and dynamo sets, 225.
Garbage crematory (Hering), 253.
Steam engine apparatus, Manchester school, 472 (†).
Timber:
For bridge flooring, 426.
Tests of pine and fir, 103.
Toronto, Ont.:
Asphalt pavement repairs, 320.
Concrete sidewalks, 619.
Public work bids by city engineer, 397.
Towers:
Fall of campanile, Venice, 135, 152, 229 (†).
Traction:
Conversion from steam to electric; Cincinnati, Georgetown & Portsmouth R. R., 16.
Highway, 330.
Trade publications: 17, 64, 112, 209, 233, 281, 329, 377, 425, 473, 545.
Tramways:
(See Railways.)
Transformers: Fire resisting properties, 604.
Travelers:
Rio Grande, Costa Rica, bridge, 309 (†), 434 (†), 515.
Steel, for erecting the Uganda Railway bridge, 105 (†).
Used on Eighteen-Mile Creek viaduct, 266 (†).
Trees:
San Jose scale on, 579.
Truro, Nova Scotia: Concrete sewer, 196 (†).
Tunnels:
Brooklyn-Manhattan underground, 29, 73.
Cleveland water-works, progress of, 588.
Coal conveying, Babcock & Wilcox shops, 529 (†).
Concrete for pipe subways, University of Nebraska, 62.
East Boston lease, 395.
For large sewer, Brooklyn, 226.
Inspection of Niagara Falls Power Co.'s tunnel, 185.
Los Angeles, Cal., tunnel for water supply, 40.
Millwall-Greenwich, London, 149.
Pipe, Prudential buildings, Newark, 367 (†).
Pittsburg & Lake Erie terminal, for pipes and electric wires, 98 (†), 152 (†).
Simplon tunnel, work on, 279.
Skaguay tunnel for pipe, 50 (†).
Weston aqueduct, Boston water-works, 362 (†), 386 (†).
(See also Subways.)
Turbines, Steam:
750-h. p., Newport, R. I., 401.
Test of De Laval, using superheated steam, 100.
Turbines, Water.
European water-power plants, 460 (†).
Rockwood-Allen flow recorder, 610 (†).
Vouvry power plant, 516 (†).
Typhoid fever:
Antagonism of soil bacteria to typhoid bacillus, 440.
Influence of water supply, 485.
Oyster culture near sewer outfalls, 569.

U

University of Illinois: Lighting for five new buildings, 232.
Uralite:
Fire test of, 584.

V

Valves:
Trane vacuum, 136 (†).
Vaults: Dampness in, 234.
Ventilation:
Akron jail, 518 (†).
Ansonia apartment hotel, New York, 467 (†).
Bush Temple of Music, Chicago, 445 (†).
C. & C. Shaft, Virginia City, Nev., 171 (†).
Drafts in Detroit schools, 113.
First National Bank, Uniontown, Pa., 13 (†).
Gimbel department store, Philadelphia, 565 (†).
Pittsburg & Lake Erie terminal, Pittsburg, 98 (†), 152 (†).
Pratt Institute, Brooklyn, 495 (†).
Rochester Athenæum and Mechanics' Institute, 60 (†).
School No. 23, Rochester, N. Y., 278 (†).

Stecher Lithographic Co., Rochester, N. Y., 297 (†).
Washington Heights library, New York, 615 (†).
Worcester High School, Mass., 182 (†).

W

Washington, D. C.:
Hand sweeping machines, 326.
Improvement of (Am. Inst. Arch.), 577.
Water consumption, 587.
Water waste, 231.
Water:
Action of distilled on lead, 480.
Analyses of Westfield River, Springfield, Mass., 35.
Apparatus for collecting samples at various depths, 137 (†).
Character of, for irrigation, 583.
Cost of the pumping of, Boston, 151.
Flow of, in pipes, 529.
National control of non-navigable streams, 492.
Purification of sea, 608.
Rust stains resulting from crenothrix, 75.
Study of quality by U. S. Geological survey, 152.
Vitality of bacteria, 440.
Water clarification:
Experiments at St. Louis, Mo., 32 (†).
Water consumption:
Boston, 618.
Chicago, 610.

THE ENGINEERING RECORD,

BUILDING RECORD AND THE SANITARY ENGINEER.

VOLUME 46. NEW YORK, JULY 5, 1902. NUMBER 1.

TABLE OF LEADING ARTICLES.

The Panama Route for an Isthmian Canal...... 1
The U. S. Refrigerating Plant at Manila, P. I. (Illustrated) 2
Standard Cement Specifications.................. 4
Some Features of the Works of the Stanley Electric Mfg. Co. (Illustrated).................. 6
The North German Lloyd Pier-Sheds, Hoboken.—III. (Illustrated)........................... 8
Moving a Long Railroad Bridge at New Brunswick, N. J. (Illustrated)..................... 10
Underpinning a Tall and Narrow Brick Building. (Illustrated) 11
The Mechanical Plant in the First National Bank, Uniontown, Pa. (Illustrated)............ 13
Water Supply in the Carnegie Residence, New York. (Illustrated)............................ 14
Two Pumping Devices. (Illustrated)............ 17

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The Panama Route for an Isthmian Canal.

The selection of the Panama route for an Isthmian Canal to be constructed by the United States is, in fact, so successful a piece of engineering as properly to be called a triumph for that profession. The selection, it is true, is to a certain extent qualified. The Spooner amendment of the Hepburn Bill authorizes the President to construct a canal on the Panama route if he can secure a satisfactory title from the New Panama Canal Company to its property and rights on the Isthmus, the sum to be paid not to exceed $40,000,000. His authorization for the construction of a canal is further conditioned upon securing from the Republic of Columbia for such sum as may be agreed upon, "perpetual control of a strip of land, the territory of the Republic of Columbia, not less than six miles in width, extending from the Caribbean Sea to the Pacific Ocean, and the right to use and dispose of the waters thereon." If he should find the title offered by the French Company unsatisfactory, or if the Columbian Government should prove to be obdurate or unreasonable in its demands for compensation for the rights and privileges necessary to the United States, he is authorized to select the Nicaragua route for the canal provided satisfactory terms can be made with the governments of Nicaragua and Costa Rica. As a matter of fact the constitution of the Republic of Costa Rica must be changed before the desired rights and privileges can be secured by the United States. This difficulty could probably be overcome without great delay, but it requires a public action not yet taken by the government of Costa Rica.

There is little or no reasonable doubt that the government of the Republic of Columbia will without material delay enter into the necessary treaty agreements, and it has been shown by the Isthmian Canal Commission, confirmed by the most careful examination of the matter as disclosed by the arguments in the Senate, that the title offered by the New Panama Canal Company is in every way valid and satisfactory. There are practically two parties on the French side in the purchase of the new Panama Canal Company's property and rights, i. e., the New Panama Canal Company and the liquidator of the old company, the latter being a large holder of the shares of the New Company. The liquidator represents all the claims which the shareholders of the old company can have on the new property. He can act in the disposal of those claims only under the direction of the French Court called the Tribunal Civile de la Seine, and he has the authorization of that court to assent to the sale of the property and rights of the new company to the United States. The New Panama Canal Company is a corporation with power to dispose of its property after due process as prescribed by the French law, and its action has been taken comformably to that process. There can therefore be no reasonable doubt of the validity of the transfer, but under the act passed by both Houses of Congress, the President is to satisfy himself beyond doubt that the title is of such a nature as to be valid and as to shut off all claims whatsoever from either the old shareholders or the new.

There is obviously a possibility of difficulties or delays in dealing with any or all of the Central American governments in interest. Indeed, there is just the possibility of concerted action through secret agreement between them to secure, to their mutual advantage, an extortionate amount from the United States Government for the requisite concessionary rights. Although this is too remote a development to need serious present consideration, should it arise there are conceivable methods available by which the United States could meet it in an effective and conclusive manner. Aside from that feature of the matter, which will probably not arise, the President is now in a position of great advantage in dealing with the whole question. He can proceed with absolute freedom in meeting every possible exigency of the case. There is neither disposition nor desire on the part of the United States Government to take any advantage of any of the three Central American Governments whose territories include the land required for these two routes, but on the other hand there is no intention whatever of being imposed upon by an attempt to exact exorbitant terms for the requisite concessions, and that is one element of the question on both routes which might as well be recognized at once.

The people of the United States have determined to build an Isthmian canal. When the Isthmian Canal Commission was appointed to make an absolutely thorough and complete examination of both routes in a fair spirit and without prejudice, the sentiment of the country was without doubt almost entirely in favor of the Nicaragua route. Indeed, it is probably correct to state that the great majority of engineers qualified to pass judgment upon such questions, who had given much attention to the Isthmian Canal problem, would also have declared against the Panama route and in favor of that in Nicaragua. Many strong influences of various kinds had operated to bring about this result until in one way or another the impression had become firmly lodged in the minds of the great majority of the American people that the construction or ultimate completion of the Panama Canal was beset with difficulties practically insurmountable. Among other things it was supposed that the floods of the Chagres River were substantially uncontrollable and certain to work destructive damage to the canal, either in stages of construction or as completed. The exceptionally complete and thorough examination of the Isthmian Canal Commission, both in the field and by the aid of analytical engineering procedures, have shown with the conclusiveness of actual demonstration that every supposed insurmountable difficulty of construction on the Panama line is imaginary; that construction by that route as a whole, taking every item and every feature of environment, is actually more simply feasible than construction by the Nicaragua route. A number of the principal quantities are far larger in amount on the latter than on the former, and the total cost is correspondingly greater, as is also the time required for completion. The time of passage through the Canal and annual costs of maintenance and operation are largely in favor of the Panama route. In short, the engineering work of the commission has been done with such completeness and fairness as to guide the sentiment and choice of the American people to the wisest and best interoceanic waterway, and that result may well be termed a triumph of civil engineering. It is to be hoped that the construction of the canal may be begun as early as practicable and that the way may be opened to an early completion of this great engineering work.

Stoppages of Sewers by roots of trees made it necessary to relay over 19,500 feet of clay pipes in the system at Berlin, Germany, in 1900. The joints are now made with oakum and asphalt in order to avoid such trouble on new lines.

The Paper on Reinforced Concrete Beams by Professor Hatt, printed in The Engineering Record of June 28, contained an important error, not detected until the edition was printed. The first sentence at the top of the middle column of 603 should read: "This fact has been determined by M. Considére, who says that plain concrete breaks in tension with an elongation of 1 part in 10,000, while reinforced concrete breaks with an elongation of 1 part in 1,000." The author has also added a seventh conclusion to the paper, as follows: "The tensional strength of the concrete is an important factor in the computation of deep beams of reinforced concrete."

The Minnesota Drainage Commission has charge of a system of ditches in the Red River valley which has been the means of reclaiming a large amount of swamp and meadow land of little value except when drained. The work of the Commission, of which Prof. W. R. Hoag is chief engineer, is well told in its last report, which also contains a brief memorandum of a creditable act of the chairman, Mr. Ezra G. Valentine, deserving wider circulation than the report gives. The maintenance of these ditches requires a considerable annual sum, and as the State neglected to appropriate the needed money, this gentleman himself gave for the work the amount the Legislature was asked to grant.

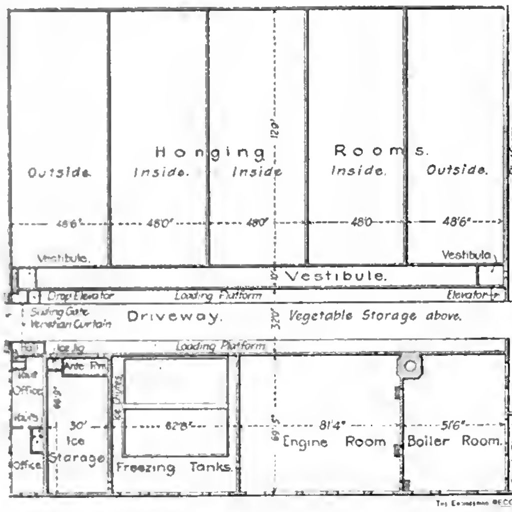
The U. S. Refrigerating Plant at Manila, P. I.

The War Department of the United States has now in operation at Manila, P. I., a large ice-making and refrigerating plant of unusual interest, erected to supply the army and navy stationed in the Philippines with practically the same food they would get if on duty in this country. It was erected at a cost of about $250,000, and has a capacity of 5,000 dressed cattle, 7,000 dressed sheep, 100 tons of bacon, 50 tons of butter and 100 tons of vegetables, besides a plant for making 40 tons of ice daily. The building is about 245 feet square and two stories in height, a higher structure not being advisable on account of the prevalence of earthquakes in that region. In its exterior, an effort has been made to give the architecture as pleasing an effect as possible, and a tall chimney that was adopted to produce draft and carry away the gases of combustion is surmounted with a statue of the Goddess of Liberty and the shaft finished to represent a lofty column.

The plant comprises a boiler room, an engine room, the freezing room, and an ice storage room, extending in line on one side of the building, and two floors of refrigerated, or, as they are termed, hanging rooms, with a driveway between them and the mechanical plant on the ground level, a vegetable room over the driveway and a loft above for insulation from the heat of the sun by means of the air space. The hanging rooms are thus well separated from the boiler and machine rooms, with their necessarily high temperature, and are reached from a corridor or vestibule, parallel with the driveway on each floor, and are not directly open with the outer air. The vestibules at one end are served by an electric elevator built by the Eaton & Prince Company, of Chicago, and at the other end by a hand-controlled drop elevator for lowering material from the hanging rooms. The building is built of red and yellow brick trimmed with stone.

The boiler plant consists of three 200-horse-power Babcock & Wilcox water-tube boilers, two in one battery and the third in an independent setting. Each boiler has a total heating surface of about 2,000 square feet and is fitted with Culver Corliss grates of 40 square feet of grate surface, for burning Japan coal. The coal is stored in a shed extending from the boiler room and dumped in piles in front of the boiler as needed, the firing space or distance from the front of the boilers to the building wall being about 21½ feet, or sufficient to remove any of the tubes. Besides the boiler there are two fire pumps and a boiler feed pump in the engine room, which is 51.5x69.5 feet in plan.

Natural draft is provided for the boilers by means of the ornamental stack mentioned. This is a combination brick and self-supporting steel stack, the brick portion extending through the building and the steel part rising clear above it. The total height of the chimney proper from the boiler-room floor line is 152 feet, while from the arc lamp held in the hand of the Goddess to the boiler room floor is 170 feet. The stack is lined with firebrick to within 25 feet of the top, and the inside diameter throughout the lower part is 5 feet, while that above the lining is 6 feet. The lower part of the brick portion is 14.5 feet square and the upper part octagonal. The steel portion rests on a sectional cast-iron ring and is anchored against it to the brickwork by means of 16 1¾-inch anchor bolts spaced around on a 10½-foot circle. These are 62 feet 4 inches long except at the smoke inlet from the boiler breeching. The firebrick lining through this part of the stack is 8 inches thick and separated from the main brickwork by 4 inches of air space.



PLAN OF THE PLANT.

Above the brick portion the steel flue has the usual flaring bottom and the firebrick lining continues through it 4 inches in thickness, leaving 2 inches air space between it and the steel work. About 35 feet of the lower part is hidden in an elaborate covering of No. 16 galvanized iron formed to represent the bottom of a column, and for this part of the structure the regular lap joint seams are employed in connecting sections of the steel work. Above that, however, in order to leave the exterior free from any projections, butt joints were employed with cover plates inside and rivets countersunk flush with the surface. The steel plates are $^7/_{16}$ and ¼-inch thick at bottom and top, respectively. For the support of the statue a skeleton globe of tee iron immediately surmounts the stack; at its equator is attached a 3-inch 6-pound I-beam which acts as a track for a man hoist. The hoist comprises a trolley from which is suspended a 6-inch pulley carrying the rope by which the man is lifted up and down.

Steam is generated at 160 pounds pressure and is carried from each boiler in 8-inch copper pipe built to withstand that pressure, and bent in a 4½-foot radius. These connections feed into a 10-inch main overhead in the rear of the boilers. Each connection has a single stop valve in the horizontal portion and is suspended from the roof beams of the boiler room by long rods carrying hangers with rollers for the easy movement of the pipes. Steam is taken from the 10-inch main from each end, at which point is a Cochrane separator. At one end it feeds the two pumps in the boiler room and from the other the other pump in that room and a 10-inch main which is carried below the floor of the engine room for the ammonia compressors and auxiliary machinery.

The engine room contains three 125-ton refrigerating machines, a 5-ton auxiliary refrigerating machine, a 150-horse-power steam engine, an equipment of power pumps driven by means of shafting from the steam engine, a 40-kilowatt direct-connected and a 30-kilowatt belt driven electric generator, a duplicate system of coke filters and condensing apparatus for the exhaust steam and a feed-water heater. The refrigerating apparatus is of the compression

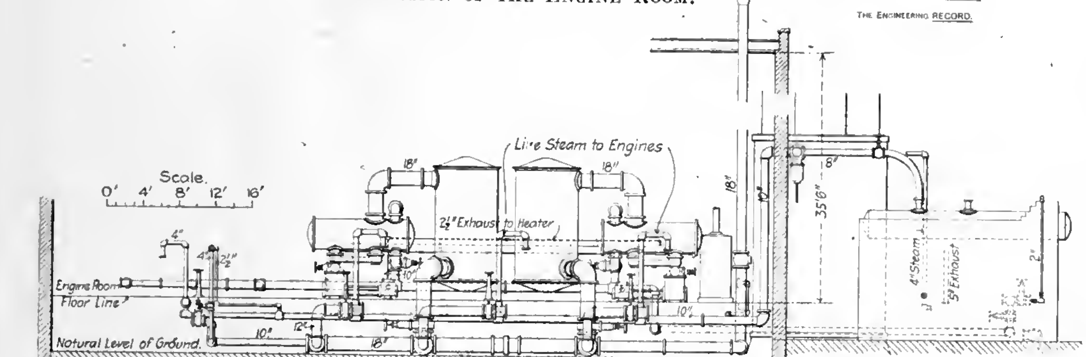
Cross-Section of the Engine Room.



Plan and Elevation of the Boiler and Engine Rooms.

type. Each of the large compressors have tandem, compound, horizontal, Corliss, steam ends, 19 and 38x32 inches in cylinder dimensions and double acting vertical ammonia ends, 14½x32 inches in size, the cylinders side by side. The machines were built by the De la Vergne Refrigerating Machine Company, of New York City, and are of their standard type, employing vertical A frames for the support of the ammonia compressors, and a flywheel 13 feet 4 inches in diameter. The small compressor has a 6½x11-inch double-acting ammonia cylinder and a 10½x7¼-inch steam cylinder.

The 150-horse-power steam engine is of the tandem compound Corliss type built by De la Vergne Company. It runs at 80 revolutions per minute and has a 12-foot flywheel which is used as the driving wheel carrying two belts passing to two jack shafts. To avoid obstructing the floor any more than necessary, the jack shafts are supported overhead. As already stated the various pumps in the room are belt driven, the type being chosen to obtain a number of comparatively small units, which would be more or less expensive in the amount of the steam consumption if steam actuated, and their adoption was also made to secure a compact arrangement without the complexity of numerous steam, exhaust and drip connections. In the one case the engine drives a counter shaft to which are belted three 7x8-inch double-acting pumps to deliver water to the ammonia condensers and a smaller single-acting boiler feed pump; in the other case, it operates three circulating pumps for the condensers of the steam engine and a 2½x4-inch fresh water pump. The pumps were all built by the Stilwell-Bierce & Smith-Vaile Company, and the circulating pumps are run at 250 revolutions per minute, the speed of the counter shafting. In addition to the pumps the 30-kilowatt electric unit is driven by belt from one of the shafts. This is a General Electric direct-current machine to supply current for lighting and for various motors. This dynamo and all the pumps are connected to the jack shafts by means of clutch pulleys.

Although the various pumps mentioned are all belt driven and thus dependent on the continuous operation of the 150-horse-power steam engine, provision has been made by cross-connecting the piping for the fire pumps in the boiler room to take the place of the circulating pumps and the boiler feed pump in the boiler room to substitute for the power feed pump. The fire pump at one end of the boiler room is connected to the ammonia condenser system and that at the other end to the steam condenser system. They are 18x10x12-inch duplex Stilwell-Bierce & Smith-Vaile pumps and have a rated capacity of 1,000 gallons per minute. The steam boiler feed pump is 8x5x10 inches in size. The belt driven generator is likewise accompanied by the independent 40-kilowatt unit, which is a general electric marine type direct-current set, arranged to feed the system supplied by the belt-driven machine. The engine room is served from a hand power traveling crane of 25,000 pounds capacity, built by Maris Brothers of Philadelphia, having a span of nearly 48 feet and leaving a clear height from the floor of the engine room of 24½ feet.

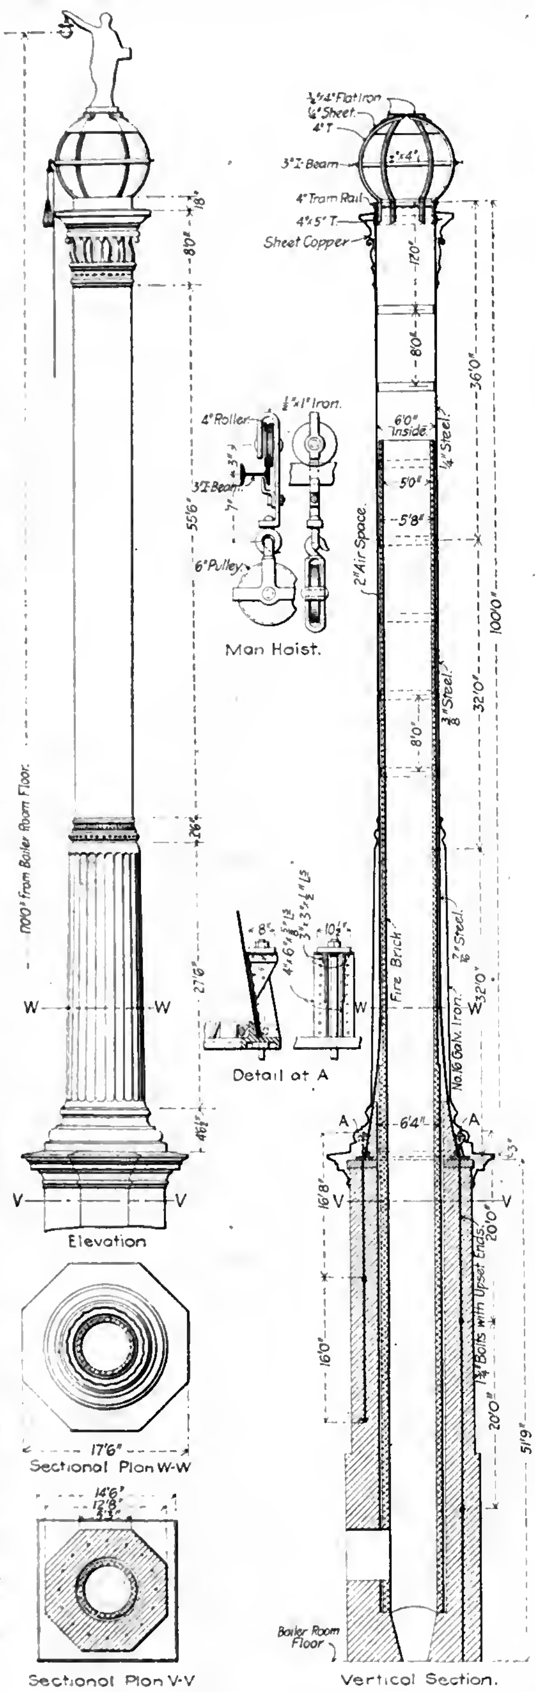
Both steam and exhaust connections to the machines in the engine room are made under the floor, the valves having extended stems and ordinary floor stands. The exhaust is collected into an 18-inch header, passes through two 18-inch connections to two coke filters and thence reaches the condensers, one connected to each filter. Arrangements have been made in the disposition of the condensed steam to return all or part to the boilers for conversion into steam again or into a distilling plant for use in cans in the freezing tank room, the can system of ice making being employed, which requires water free from air to make transparent blocks of ice. The coke filters, which contain Connellsville coke, are 7 feet in diameter and 15 feet high. The condensers are Wainwright surface condensers made by the Taunton Locomotive Manufacturing Company and each has about 1,400 square feet of cooling surface which was calculated on a factor of 2.6 square feet of cooling surface per horse-power, each horse-power being defined as the equivalent of 15 pounds of steam per hour. Each condenser is operated in connection with a 10x16x18-inch Deane direct-acting steam air pump. Water from the Rio Pasig is used for condensing purposes and is received at an average temperature of 85 degrees Fahrenheit. An equipment of triplex pumps is installed for the condensing water, as stated, with provision to use one of the fire pumps when necessary, and the water is drawn from a settling well or cistern 12 feet in diameter and 14 feet deep. In the proportions of the condensing system, a temperature range in the condensing water of 30 degrees was allowed for.

The feed water may be delivered to the boilers by means of a direct-acting steam pump in the boiler room or a triplex pump in the engine room, both drawing from the feed-water heater, which is a Cochrane feed-water heater, made by the Harrison Safety Boiler Works, of Philadelphia. The triplex feed pump is also cross-conected with a sweet water pump, likewise of the triplex type, alongside the steam condenser pumps, for furnishing water for the freezing cans, the suction connections for this purpose coming from the condensers before the water passes to the heater. As stated, the condensed steam that is drawn from the condenser and frozen in the cans is distilled for the removal of air and impurities in order to produce ice as transparent as possible. The distilling apparatus is located in the freezing room and consists of a skimmer in which the impurities are floated off, of a reboiler the office of which is principally to expel the air, a cooler to condense the re-evaporated water, a deodorizer containing hardwood charcoal for the purpose that its name indicates, and cold water storage tanks from which the freezing tanks are filled as needed.

This apparatus is distributed on three floors in the freezing room. The fresh water pump in the engine room delivers to the skimmer, which, with the reboiler, occupies the highest position. The overflow from the skimmer, which carries off the foreign substances, is led to an overflow tank on the floor below. In this the water has a further chance to clarify itself, and it is then led back to the feed-water heater for use in the boilers. The tank is provided with an overflow to the sewer, and a constant water level is maintained by means of a float valve admitting fresh water whenever necessary. From the reboiler, which is equipped with submerged steam coils and a vent to the atmosphere for the escape of air, the steam flows to the cooler on the floor below, which is a pipe condenser of 640 feet of 2-inch pipe. The condensed water then passes through the deodorizers and thence to two cold-storage tanks immediately above the freezing tanks. Each of these contains a submerged ammonia coil for cooling the water before emptying it into the cans.

The ammonia distributing system represents the standard practice of the De la Vergne company. The ammonia condensers are located in a room above the engine room the full length of the latter and about 32½ feet wide. There are altogether three sets of 13 condensers each, corresponding to the three compressors, each condenser consisting of 2-inch pipe 24 pipes high and 20 feet long. The ammonia gas from the compressors is carried into a header from which each condenser is supplied and which can be divided into three sections by valves. The condensing water is delivered in an 8-inch pipe feeding a 6-inch header passing in opposite directions across the condensers with 1¼-inch pipes for each condenser. Fresh water is used in this condensing system and the warm water is utilized partly for sprinkling the ice cans to remove the frozen cake and partly being sent to the feed-water heater through the overflow tank in the distilling plant.

The freezing room contains two tanks capable of a daily output of 20 tons of ice each. The can system is employed, as stated, with the cans immersed in brine which is cooled by the direct expansion of ammonia. The tanks are 52.5 feet long, 23¾ feet wide and 4 feet deep, and each contains 112 lengths of 2-inch pipe 49 feet 3 inches long. The pipes are connected by return bends and are placed in rows 16 inches on centers and six pipes high in general, forming 16 alleys or longitudinal spaces in which the cans are placed. The coils in each tank are supplied with liquid ammonia at four points and the suction from them at four intermediate points. A propeller fan is provided for each tank to circulate the brine, each driven from a 3-horse-power motor. Each tank is spanned by a crane 24 feet 2½ inches span, carrying a pneumatic hoist for handling the ice. The compressed air for this purpose is furnished by two New York air brake air compressors. At the far end the ice is dumped from the can upon an ice chute by which it is delivered to the ice storage room adjoining,



DETAILS OF THE CHIMNEY.

where it can be loaded on wagons or kept indefinitely.

The proportions of the refrigerated rooms of the plant are as follows: The ice storage has two levels of 2-inch pipes on the ceiling and the ratio of cubical contents in cubic feet to cooling surface in square feet is 16 to 1. The vegetable room, which is over the driveway, 30 feet 4 inches wide, 128 feet long and 11 feet high, has four lines of pipe on each side wall toward the ceiling, and seven lines, each four pipes deep, on the ceiling; the ratio is 16 to 1. Each of the hanging rooms, which are 47x129x11 feet in dimensions, have the pipes arranged above the usual false ceiling to set up an internal circulation of air. In the case of the four outside hanging rooms, that is those at each end of the building on the first and second floors, the ratio is 8 to 1; and in the case of the six inside rooms it is 10 to 1. The hanging rooms are entered from a long vestibule in which the valves to the cooling coils are all controlled.

Each room is fitted with overhead tracking with the main lines running down the vestibules. The entire tracking system comprises 25,000 feet of track, 15,000 hangers, 12,000 trolleys and 1,000 ball-bearing switches furnished by the New Jersey Foundry and Machine Company, of New York City.

The original plans for the plant, which is known as the Insular Cold Storage and Ice Plant, were drawn under the supervision of the Quartermaster Department of the U. S. Army, for which Messrs. Frank L. Strong and Edward Barrath, of Chicago, were consulting engineer and consulting architect, respectively. The general contract was awarded to the De la Vergne Refrigerating Machine Company, of New York, which designed the details of the plant as described. Maj. Leon S. Roudiez, U. S. A., under whom the work was completed, is in charge of the plant.

Standard Cement Specifications.

A paper read by Mr. R. W. Lesley, Assoc. Am. Soc. C. E., before the American Section of the International Association for Testing Materials.

Of the making of specifications, there is no end. This, at least, is the experience of the cement manufacturer, whose material, instead of being tested according to lines thoroughly well settled, as in the iron and steel business and tested at the place of manufacture, as is the practice in other businesses, is subjected to endless variations of tests, which are frequently made thousands of miles away from the point at which the goods are produced. The material tested is not the material that leaves the works, as its form and character are changed by making it into briquettes, test pieces, etc., neat and with sand, and it is subjected to all sorts of manipulations, so that the results obtained frequently vary materially from those made under similar conditions at the place of manufacture. Consequently, there is no industry worse off, for definite specifications, than the cement industry, and none has suffered more than that industry from the lack thereof.

It is with pleasure, therefore, that I am here to address an Association the purpose of which is the standardizing of testing and methods of testing, and it is my pleasure in addressing it to state, in a very general and brief way, some of the disadvantages that the cement industry has labored under during the formative period of tests which has been going on in this country, and some of the many advantages that would accrue as well to the manufacturer, the user, and the engineer and architect, by the adoption of standard methods and the correlation of different standards and specifications adopted by the various classes of engineers and consumers using the material.

In my office, I have a large fireproof safe containing many volumes of filing cases, solely devoted to the embalming in fireproof receptacles of specifications that have come to me at various times during my business career. These specifications are of all kinds and of all characters, mostly good but some few bad and indifferent, containing elements of every imaginable description, both as to the requirements and as to methods of handling the material in arriving at the requirements suggested. This is the mere literary side of cement specifications that I have in my office.

The practical side of this business is at our laboratory at our works. This laboratory, quite a large room, say, 20x20 feet, a few years ago was entirely papered on its four walls with cement specifications. One wall was devoted to the specifications of the army engineers of the United States Government, well considered, well thought out and well reasoned specifications, all of them. Another side was almost covered with specifications of the United States navy engineers of the Bureau of Yards and Docks and other bureaus of the same department; all specifications thoroughly thought out, well planned, well conceived. At the other end of the room, the pattern varied somewhat, and there were gathered the requirements as to quality and the methods of manipulation of cement testing to be done by the various railroads of the country. They were more concise, more brief and more to the point, but all of them intelligent, able and well drawn. On the other side of the room, surrounding the door, were grouped a more general gathering of these interesting documents, and embraced what the city engineers all over the country and the engineers of large municipal works in the United States thought should be required of cement, and how it should be handled in arriving at these requirements. Needless to say, this series of patterns embraced a larger variety and covered a larger area of territory, and, like the others, represented careful, hard work, and well conceived and well balanced requirements.

Individually, almost any one of the specifications on the four sides of that room, could be picked out at random, as a fair, reasonable specification of what Portland cement should be. Almost any one of them could be used with advantage and with success and, with few exceptions, any one of them could be carefully scrutinized and nothing seriously ill-judged or unbalanced could be found within its lines.

It is a remarkable tribute to the engineering ability of our country that when all these specifications which covered the four sides of a room and running into the hundreds in number, are gone over carefully, that there are so few which will not stand the test of careful examination and scrutiny, and the conclusion is to be clearly drawn from the facts above stated, that it is not so difficult for intelligent engineers to make a specification containing the proper requirements for fineness, tensile strain, time of setting, constancy of volume and specific gravity and for proper manipulation of the several tests described. Yet with all these facts before us, it is actually possible that within a single year, a single large cement establishment like our own, receives no less than 100 to 150 of different kinds of specifications, varying in most all their elements.

Taking an assortment of specifications at random and in examining all of them to see just how they did vary, I find that taking the four great classes, the army, the navy, the railroads and the various cities, there were:

In some 25 specifications of various cities of the United States, 7 variations in the item of fineness alone, 14 variations in the requirements of tensile strain, and 6 variations out of 9 requirements in reference to setting-time. In the specifications of the army, some 68 in number, I find some 14 variations in tensile strain, 11 variations in fineness, 7 variations in time of setting, and 4 in constancy of volume. In the specifications of the navy, some 7 in number, there were 3 variations in fineness, 5 in tensile strength, with no variation in the time of setting. Among the railroads, of which 8 specifications were found, there were 5 variations in fineness, 5 variations in tensile strain and 3 variations in the time of setting.

As to boiling and hot tests, I took some 35 requirements of these tests gathered from my specifications, and out of these 35, in 10 the pats go into water after 24 hours, in 14 the pats go into water after no specified time, and in 11 the pats go into water after setting. Again, out of these 35, in 6 the pats go into steam for 3 hours, in 14 the pats go into hot water for no specified time, in 1 the pat goes into hot water for 3 hours, in 2 the pats go into hot water for 30 minutes, in 1 the pat goes into hot water from 24 to 36 hours, in 8 the pats go into hot water for 24 hours, in 1 the pat goes into hot water for 10 hours, and in 2 the pats go into hot water from 24 to 48 hours. Again, out of these 35, in 21 the pats go into boiling water, in 4 the pats go into a temperature of 212 degrees, in 6 the pats go into a temperature of 176 degrees, in 1 the pat goes into a temperature of 170 degrees, in 1 the pat goes into a temperature of 100 degrees. Finally, out of these 35 specifications, in 13 the pats are to boil for time not specified, in 2 the pats are to boil 30 minutes, in 1 the pat is to boil 3 hours, in 1 the pat is to boil 24 to 36 hours, in 3 the pats are to boil 24 to 48 hours, in 1 the pat is to boil 10 hours, in 5 the pats are to boil 24 hours, in 1 the pat is to steam 3 hours, then stay in hot water 48 hours, and finally to boil one hour; in 1 the pat is to steam 3 hours and to boil 48 hours, in 4 the pats are to steam 3 hours and remain in hot water 48 hours, in 2 the pats stay in hot water 48 hours, in 2 the pats stay in hot water at 176 degrees for 24 hours, and in 1 the pat stays in hot water at 110 to 115 degrees for 24 hours. From this it can readily be seen, from the manufacturer's standpoint, that not only the pat, but the manufacturer himself is in "hot water" for all sorts of indefinite periods of time.

Now, just for one moment, imagine the manufacturer's plight while trying to make a cement during the course of a short period in which these specifications were received, which would meet all these different requirements and conditions, and then you can see at a glance, how important it is, not only that there should be a standardizing of methods, but that there should be a standardization of specifications. I am happy to say that two departments of our Government have already taken this step, and where one wall was formerly covered with the specifications of the United States army, that wall is a blank with the exception of the one specification [see The Engineering Record of September 14 and 21, 1901], recommended by the army board, composed of Major W. L. Marshall, Major Smith L. Leach, and Captain Spencer Cosby, and approved by the United States Engineer Corps. This shows the result of the good work of a very capable force of good engineers.

The other wall, formerly having as its decoration the productions of the engineers of the navy, is to-day practically a blank space, with a single ornament in its center, namely, the small frame containing the specification of Rear Admiral M. T. Endicott, U. S. N., giving the requirements for all the work of the United States navy, [see The Engineering Record of February 4, 1899]. These two Government specifications are not quite alike but in many of their elements are at least within "shooting range" and it is possible to meet them, without performing the gymnastic feats in manufacturing which were requisite to meet the requirements of the many varieties of predecessors they had on our walls.

We still have with us the railroads and the municipalities. The railroads are taking a step in the same direction as these two branches of the Government, and while there has not been a formally adopted specification of all the railroads in this part of the country, the last convention of the American Railway Engineering and Maintenance of Way Association adopted a tentative specification [see The Engineering Record of April 12, 1902], which represents much good work and is in the line of standardization in that department.

The cities and commonwealths of the country, in the execution of their large work, have not yet arrived at the standardization of specifications, but we have hopes that it will come next.

Now what I want to make clear, after having gone through this underbrush of discussion, is that this Society of ours has within its hands a golden opportunity in the field of cement specifications. The army, the navy and the railroads have all gone forward in the proper lines and are practically committed to forms of specifications embracing requirements for the various elements and properties and for methods of manipulation giving reliable results by the respective tests suggested. The American Society of Civil Engineers has appointed a committee to determine upon the proper manipulations of tests of cement, and this committee, several of whose distinguished members are with us to-night, has been laboring with this subject for several years and I understand will shortly report.

Now our Society cannot, with loyalty to itself or regard for its fellow society and the engineers of the Government and the railroads, undertake to undo or criticize the work that these bodies have done. It cannot with propriety adopt new methods of manipulation while so distinguished a body as the American Society of Civil Engineers has this subject under consideration. It cannot of its own motion set up new standards and new requirements, while the army, the navy, and the railroads have come to conclusions of their own on this subject. But this Society of ours, international in its features, can at a time when the export trade in this country in cement is increasing at the rate of five hundred per cent. a year, take steps in co-operation with army and navy engineers and the American Society of Civil Engineers and in co-operation with scientific bodies abroad, to arrive at some method by which a correlation of the specifications of this country and Europe may be reached and results obtained whereby cement manufactured at any point of the world may be tested under similar methods of manipulation and subjected to similar tests at any point where it may be delivered. This cannot be done by independent action, but it must be done by suggestive and persuasive action, and with the support and cooperation of the bodies who have preceded us in the field and have carried out independent investigations on their own lines. It can be best done by the organization, under the auspices of this body, of a cement section, which shall have among its membership representative engineers of the principal consumers of cement, distinguished testing engineers representative of the various well known testing laboratories, and also representatives of the leading manufacturers. Such a section, comprising in itself representatives of the consumer, the producer and the inspecting engineer, would soon arrive at proper methods for the accomplishment of the object and the work would redound to the credit of all concerned, as well as to the Society of which they are members.

The New England Cotton Manufacturers' Association will hold its seventy-third meeting at 12 West 31st St., New York, Sept. 30-Oct. 2.

Some Features of the Works of the Stanley Electric Mfg. Co.

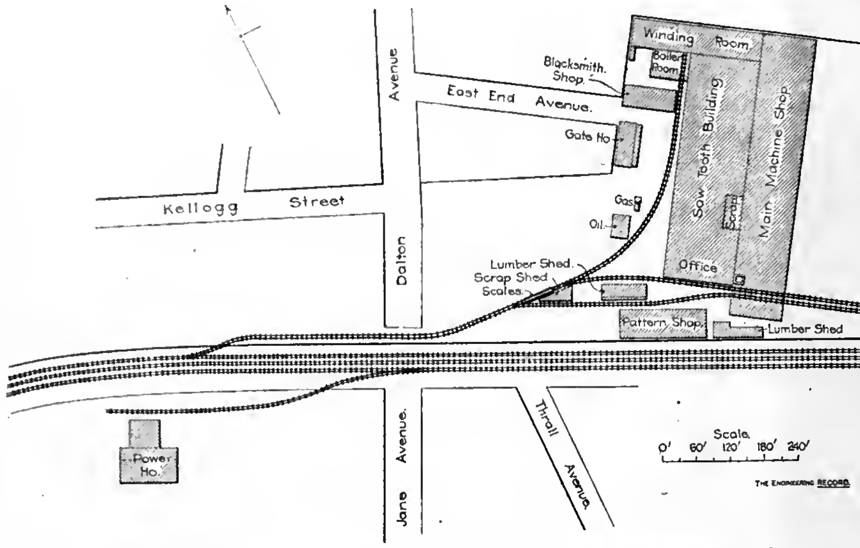
About a year ago the Stanley Electric Manufacturing Company, of Pittsfield, Mass., moved the main portion of its works into a new group of buildings situated about a mile and a half from the center of that city. Notwithstanding an ordinary provision for a gradual increase in business, however, the works have been crowded for space since their occupation; and although additions have constantly been made, operations have for some time been carried on both night and day.

The shops are electrically driven and are equipped with traveling and stationary cranes, overhead tracking with both pneumatic and hand hoists, compressed air and gas for brazing, etc. The buildings are in general lofty, well lighted by side windows and roof skylights and are painted white inside. For artificial illumination both arc and incandescent lamps are used, the latter held by brackets and floor standards, as well as by pendant wires. Automatic sprinklers are provided, connected with a system of fire mains running about the grounds with outside hydrants at different points. All departments are connected by the Clark automatic telephone system and the Rochester employes' time recording system is used.

An accompanying plan of the works shows the relative location of the different buildings. There is a main shop, 92.5 feet wide and 500 feet long, and extending laterally from this sawtooth roof building 128 feet wide. The latter is to be occupied by different departments, sections corresponding to one, two or three divisions of the roof being partitioned off for the purpose. One of these departments, devoted to coil winding, has been extended to a total length of nearly 235 feet. The main entrance to the works is located between the blacksmith shop and the gate house, the latter being a three-story structure containing general toilets on ground level, a recreation room and library for the technical information of the employes on the second floor and offices for the works' manager and others above. The plant is located alongside the Boston & Albany Railroad with sidings as shown. The power-house is situated about 1,000 feet from the center of the works, on the bank of the lake from which it draws both feed and condensing water. It is located also alongside the railroad, providing at once good railroad facilities and proximity to water.

The main building is a machine and erecting shop, about 60 feet wide in the main part with a lofty interior and a central skylight in the roof. Extending from the side bay on the first floor is the sawtooth building. The main building and bay are of steel construction, built by the Boston Bridge Works, while the sawtooth building is of brick with timber roof trusses, the skylights facing in the usual way toward the north. The main shop has two electric traveling cranes of 60-foot span, built by the Whiting Foundry Equipment Company, one of 30 tons capacity and the other of 15 tons. The longitudinal tracks are about 45 feet above the floor. Along both sides of the shop are arranged 17 pneumatic hoists mounted on swinging jib cranes. These hoists vary from 1 to 3 tons capacity. The floor is of $1\frac{1}{8}$-inch maple laid on $2\frac{7}{8}$ North Carolina pine matched plank, the latter on 4x4-inch chestnut timbers, 4 inches on centers, on 4 inches of tar concrete.

The first floor of the side bay is largely taken up with the machine shop, the largest machine tools, however, being distributed toward one end of the main building. The other end is given up to erecting and shipping work, and at about the center of the building is located the testing department. The shop contains in this portion a cast-iron floor plate on which large machine parts are finished by means of portable tools. The gallery of the bay contains most of the stamping machinery for the formation of the armature laminations and a long storeroom, besides a portion of the office, which had to find room for additional drafting space. For testing work a line of heavy shafting, to allow a motor to drive a generator and vice versa, has been erected against a longitudinal girder, as shown in the accompanying interior view of the main shop.



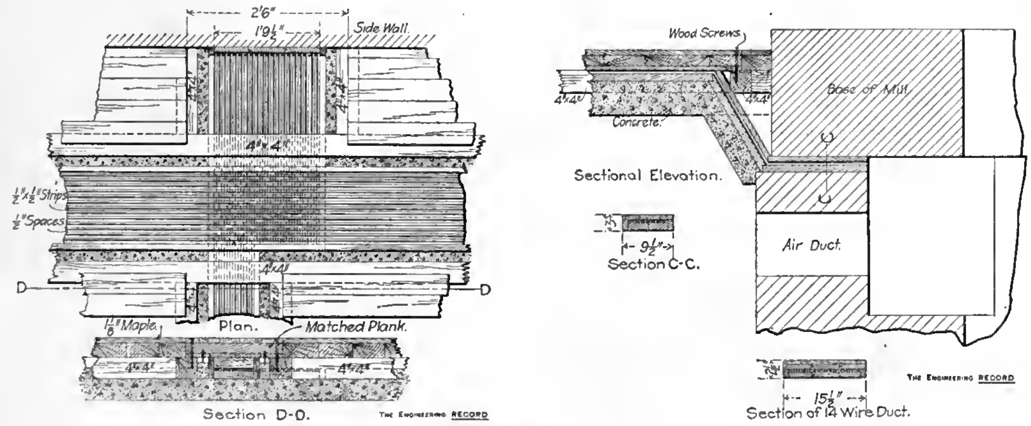
THE WORKS OF THE STANLEY ELECTRIC MANUFACTURING CO.

VIEW OF THE MAIN MACHINE SHOP.

At present castings are made outside of the works, the foundry for which ground space has been provided not yet having been built. The largest castings are brought into the main shop on the two tracks running through it at the shipping end and are lifted from the cars and carried to the desired point for machining by means of the traveling cranes. For shifting cars and storing material in the yard outside, a combination steam hoist and locomotive, built by the Brown Hoisting Machinery Company, has been provided. The locomotive hoist has a lifting capacity of 10 tons. For handling material in the gallery, there are two or three platforms extended from the gallery floor, which the large cranes can readily reach, and a 2-ton electrically operated crane furnished by Maris Brothers, of Philadelphia, which travels practically the entire length of the gallery. Its motors are controlled from the floors by means of drop cords. For passing heavy articles from the gallery floor to the first floor, there are two 4,000-pound direct-acting hydraulic elevators made by the Plunger Elevator Company, of Worcester, Mass.

The larger machine tools are, of course, driven by individual electric motors. In the case of the lathes, the grouping system is used, with ceiling motors. In one or two instances, two motors drive together a line of shafting. Each motor has four drop ropes within easy reach for its control from the floor. Wires to the machine-tool motors are in general carried in conduits under the floor, each wire having an independent duct formed by wood strips between the conductors. As indicated in the accompanying illustrations, a main conduit extends along the outside wall, and opposite each machine a number of wires are tapped; these usually run upward on the side of the wall to the controlling switches and then down to the underfloor duct leading to the machine motor.

In assembling and finishing the machinery, a large amount of chipping and drilling is done by means of pneumatic tools, and electric connections are brazed and soldered together by means of portable gas burners. For this work there are three lines of piping extending around the main shop about 25 feet above the floor level, from which are tapped branch pipes, to outlets near the floor where flexible hose connections are made. One of the pipes is for the compressed air, which is maintained at 80 pounds pressure, and the other two are for the gas, one for the gasoline vapor, brought from the gas house, so called, located in the open near the gate house, and the other for air under about 5 pounds pressure, the air being mixed with the gasoline in the flexible connections for combustion in the burners. The pneumatic tools were furnished largely by the Standard Pneumatic Tool Company, of Chicago. The air is compressed by a two-stage horizontal Ingersoll-Sergeant compressor, direct-connected to a 40-horse-power alternating-current motor. The compressor plant is located in a room partitioned off in the first story of the bay. Above its roof, it has a 3x10-foot reservoir or air-storage tank. The compressed air is also used in numerous direct-acting pneumatic traveling hoists suspended from overhead tracking; these were furnished by the Pedrick & Ayer Company, of Philadelphia.



METHOD OF CARRYING WIRES FROM MAIN CONDUIT UNDER THE FLOOR.

For artificial illumination, in addition to arc lamps, pendant incandescent lamps are used wherever convenient, but a large number of floor supports are also employed for this type of lamp, the supports consisting of vertical pipe standards, through which the wires are carried, and an adjustable rod at the top, to which the lamp is attached and held in any convenient position. Some of the lamp rods are fastened to wall brackets by a ball and socket joint. For heating, exposed lines of 2-inch pipe are used, and in the main shop, they are carried around underneath the working benches, which line the walls. For offsetting down-drafts from the roof skylight, six lines of pipe, supported by the roof trusses, run the entire length of the shop, the pipes spaced over 5 feet apart. Thus for the 13,500 square feet of skylight surface, there are about 1,875 square feet of steam pipe surface, a ratio of 7.2 to 1.

The blacksmith shop is a separate brick building, 40x94 feet in plan. In addition to the usual forge work, large transformer cases are built in this shop, constructed of riveted sheet steel. The shop equipment includes seven Buffalo down-draft forges and a Gilles & Jones bending roll electrically driven. The shop has an unusually good appearance; it has a monitor roof, and the lower parts of the brick walls inside are painted black, while above they are white.

The boiler house, adjoining the winding department, is provided to supply steam for various baking ovens and for general heating purposes, and is depressed considerably below ground surface, so that coal cars on the siding dump directly into a coal bunker underneath the track and level at the bottom with the boiler-room floor. This coal bunker is of concrete, as is the lower portion of the boiler-house walls, and has a capacity of 200 tons. There are three boilers in place, with space for a fourth, of the return tubular type, hand fired. One was built by the D. M. Dillon Steam Boiler Works, of Fitchburg, Mass., and two by the E. Keeler Company, of Williamsport, Pa. Steam is generated at 100 pounds pressure and there are two steam mains. Two Worthington pumps are installed in the room to feed the boilers, operated automatically by floats in receivers, one for the high-pressure condensation that cannot return directly to the boilers and the other for the low-pressure returns, which flow back to the receiver by gravity, as made possible by the lower level of the boilers. A single steel stack serves all boilers, which are equipped with the Spencer automatic damper regulator. An electric motor is also installed in the boiler room to operate a pump for draining a sump, to compress air at 5 pounds gauge for the brazing gas system and to actuate an ash hoist which lifts the ashes to wagons outside. The steam piping is covered with H. W. Johns asbestocel covering.

The power-house, located 1,000 feet from the shops, consist of a 54x50-foot boiler room, a 62x100-foot engine and generator room and a pump pit or basement under the latter. The plant is operated condensing and the boilers are equipped with induced draft. The jet type of condenser is used and fresh feed water is constantly taken from the lake and purified in a very interesting manner. The power house is considerably lower than the railroad, so that coal is dumped from cars on a trestle siding directly against the boiler room.

The boiler equipment is of the horizontal return tubular type, comprising four Dillon boilers, of 72-inch diameter shells 19½ feet long. A steam pressure of 140 pounds is carried. The water from the lake was found on analysis to be satisfactory for feedwater with the exception that it contained a good proportion of lime. It was therefore arranged to heat it to a high temperature before delivery to the boilers, to bring about a deposition of the lime, and for this purpose, the water is sprayed at the top of the steel cylinder into a jet of high-pressure steam taken directly from the boilers. The cylinder is 42 inches in diameter and 16 feet high, and is filled with cobble stones which present a large surface upon which the lime may deposit. The water arrives at the lime separating tank at about 200 degrees and is heated by the steam jet to about 360 degrees, at which temperature it is delivered to the boilers. The separating tank, or purifier, is of course insulated, being covered with 2 inches of asbestos. The induced draft apparatus, which includes a 60-inch fan and a direct-connected vertical engine, was furnished by the B. F. Sturtevant Company. The boilers supply steam into a header supported back of the boilers. Alongside this as an overhead walk for controlling the angle-stop valves in the steam connections and for reaching the feed-water purifier. The blow-off steam valves on the boilers are provided with pipes to the atmosphere for the escape of steam above the roof.

The engine room contains three steam engines arranged to drive a jack shaft and from that numerous electric generators. Belted generators were adopted to obtain both direct and alternating current and different frequencies of the latter by different machines, but it is intended later to replace the comparatively small units with larger machines and install frequency changers at the testing department in the main shop. The three engines are of the following manufacture: one 300 horse-power McIntosh & Seymour tandem componnd, one 100 horse-power tandem-compound engine built by the Ball Engine Company, of Erie, Pa., and one 180 horse-power Ball & Wood simple engine. The engine room is spanned by a 60-foot hand-power crane built by the Stanley Company. In the pump pit is a National feed-water heater placed in the exhaust of the large engine, a 12x18x24-inch Blake condenser, and a secondary feed-water heater for the utilization of the exhaust of the rest of the machinery. An 18x10x12-inch Knowles duplex underwriters pump is also located in the pit, having a rated capacity of 1,000 gallons per minute at 70 revolutions per minute, two 6x4x6-inch feed pumps furnished by the Warren Steam Pump Company, of Warren, Mass., and a pump for the return of clean high-pressure drips to the boilers. The live steam connections to the engines are fitted with Direct steam separators, and a Worthington meter is introduced in the feed-water line for keeping a record of the evaporation, in connection with a daily log that is taken.

In the works described, the Stanley Electric Manufacturing Company make direct-current machines as well as alternating current machines, chiefly of the well known inductor type of machine, peculiar to the company's S. K. C. system, in sizes as large as 2,500 kilowatts and for voltages as high as 12,000 volts. Transformers are also manufactured at the new works and the Stanley hot-wire indicating instruments. Switchboards and instruments in general are still made at the old works, on Clapp Avenue, Pittsfield.

The officers and heads of departments of the company are as follows: Dr. F. A. C. Perrine, president and general manager; Mr. W. W. Gamwell, treasurer; Mr. John H. Noble, assistant general manager; Mr. C. C. Chesney, chief electrician and head of engineering department; Mr. John F. Kelly, consulting electrician and head of legal department; Mr. F. R. Whittlesey, purchasing agent and head of cost department; Mr. J. H. Kelman, general superintendent; Mr. D. S. Kimball, works engineer; Mr. C. C. Morgan, manager supply department; Mr. R. W. Power, head of draughting department; Mr. W. J. Lloyd, engineer of instrument department; Mr. Gilbert Wright, engineer of switchboard department, and Mr. Ray D. Lillibridge, the technical advertising expert in charge of advertising details.

The North German Lloyd Pier-Sheds, Hoboken.—III.

The erection of the steel superstructure of the pier-sheds was commenced at the shore end of pier 2, and after all but two bents of its principal members and the fire walls had been assembled the erection traveler was shifted and resumed work at the river end of pier 1. The steel was delivered on the pier deck by two lighters with long derrick-booms which assembled the three sections of the roof trusses in blocking in a horizontal plane at a convenient height above the pier deck where the field splices were riveted up complete before erection. The brackets were also field-riveted to the columns before the latter were erected. The full-length columns, weighing about 8,400 pounds each, were first erected and temporarily held in place by two 35-foot side-booms of the traveler which extended across the end of the shed and receded before it as the successive bents of the framework were erected.

The completed roof trusses, weighing about 25,000 pounds each, were lifted by the two 40-foot center-booms of the traveler and by tackles suspended directly from the masts, and were seated on the column brackets and temporarily bolted there. The suspenders were inserted and bolted and the second-story floor-beams, each in three 10,000-pound sections, were lifted up and seated on the column brackets and bolted to them and to the suspenders from the roof trusses. The purlins and floor joists were then assembled to connect the last bent with the preceding one, and finally the monitor was erected on top of the roof trusses.

The first pair of columns were temporarily braced, just below the roof trusses on the shore side, by inclined longitudinal 12x12-inch spliced timbers about 45 feet long, and just above the top chord of the roof truss each column was guyed by two ⅞-inch wire cables in opposite directions in longitudinal planes. The bent being thus secured, the columns were released from the side booms and the traveler receded 18 feet towards the river and erected the second bent in the same way and then assembled all the principal longitudinal members connecting them, including the eaves girders and all diagonal rods. The connected benta formed a stable tower able to resist ordinary horizontal stresses, and the successive bents were erected and added to it at the rate of about nine bents in a week when there was no delay for materials.

In order to provide abundant security against possible violent winds the structure was additionally braced in the longitudinal planes of the columns by diagonal timbers and rods in occasional panels of the first and second story, and by about a dozen ⅞-inch wire-rope diagonal guys which reached across four panels horizontally and were occasionally shifted forward as the erection advanced. Ten gangs of riveters followed the erectors as closely as possible, keeping usually about four bents behind, and were in turn followed by men building the floor and roof arches and laying roof and monitor planks.

The contractor's power plant is located on shore, about 1,500 feet from the most distant part of the work, and has two horizontal tubular boilers with a combined rating of 125 horsepower. The boiler feed-water is delivered at about 50 pounds city pressure and is first used to cool the cylinders of the air compressors. This raises its temperature to 50 or 60 degrees, and it is afterwards raised in the feed-water heater to about 190 degrees before delivery to the boilers. There is a Laidlaw-Dunn-Gordon duplex air compressor with 12x12x18-inch cylinders having a rated capacity of 535 cubic feet of free air per minute. These discharge into twin cross-connected receivers from which the air is piped the full length of each pier and is delivered at 95 pounds pressure to a maximum of 18 hammers, 2 reamers and 2 oil furnaces on each pier. All field riveting, reaming and drilling was done by pneumatic tools, which were found satisfactory, rapid and economical, one gang being able to average daily 240 ⅞-inch rivets up to 5 inches long, besides building and moving their own scaffolds.

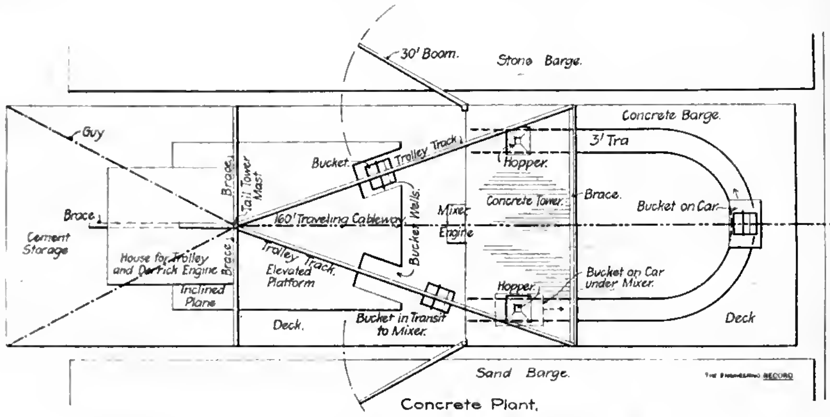
The traveler is similar in general design to that used a few years ago by the same contractors for the erection of Pier No. 13, North River, New York, and described in The Engineering Record of January 18, 1896, but differs materially from it in details. It is built entirely of timber and has two vertical braced masts and four 5-ton booms. There is a 28x74-foot trussed base, 14 feet deep, which is elevated on corner posts to clear materials stored on the deck of the dock, and supports the masts, which are set about 46 feet apart in its rear face and rise about 76 feet above the deck of the pier. The masts are carried between a pair of lattice-girder trusses about 1 foot apart in vertical planes transverse to the axis of the pier-shed, and their feet are seated on steps attached to the bottom chords of the trusses. The tops of the masts are connected by another lattice-girder truss in the same plane, and are each braced to the opposite side of the base of the traveler by a pair of divergent, stiff-legs which are connected by X-brace planks, omitted in the elevation to avoid confusion.

About 24 feet below their tops the masts are each braced by four 8x8-inch stiff-legs, two in the plane of the lattice girders and two in an inclined plane. Seats are bolted to the masts at the tops of these stiff-legs to receive the booms which have horizontal pin connections to vertical shouldered pivots. Floor platforms, about 7 feet above the pier-shed deck, are built on the lower chords of the front and rear trusses of the traveler base, and support the two three-drum hoisting engines, boilers, coal bins, etc. The vertical end-posts of the transverse trusses extend below their lower chords and are stiffened by kneebraces at their connection to longitudinal sills seated at each end on the axles of two pairs of wide-faced flangeless wheels 18 inches in diameter which roll on the longitudinal side timbers of the pier-shed deck.

The four-part boom tackles were all rove with manila rope and the fall lines of the topping lifts on the inner booms were operated by three-part tackles. At the foot of each pair of booms a nine-part wire rope fixed tackle was suspended from the mast for use in hoisting the heavy roof trusses. When the traveler was in service the tops of the masts were X-braced by wire rope guys to snubbing posts on the edges of the pier deck, several panels in advance of the traveler. These guys were tightened by hand tackles at their lower ends and were of course shifted every time the traveler advanced.

After the first pier-shed was erected the traveler on the river end of pier 2 was lifted by four nine-part steel rope tackles attached to the corners of its tower at the bottom. On each side the two tackles were suspended from the boom of a lighter derrick brought up close alongside the pier. The lighters lifted the 60-ton traveler bodily 2 or 3 feet clear of the pier and then were towed across to pier 1 and deposited the traveler on it ready to commence erection there. The traveler was out of service only about 3 hours while being moved from one pier to the other. The pier-sheds have been painted with silica-graphite paint made by the Joseph Dixon Crucible Company.

There are about 30,000 yards of concrete in the bulkhead sea-wall and in the footings of the bulkhead house. For mixing and handling this concrete a special plant was installed with a capacity to mix and handle to position about 200 yards in ten hours. The concrete had to be distributed all over the site of the bulkhead house, which is a rectangular structure 130 feet wide and 850 feet long parallel to the shore line. A large quantity of the concrete was laid in the bulkhead wall and cribs and the remaining 9,000 yards was laid in the transverse walls about 20 feet apart and perpendicular to the shore line. The plant included a special concrete barge, which was moored at any point close to the front of the sea wall, and an attached traveling cableway of 5 tons capacity and 160 feet span, which had the head-tower movable on a shore track parallel with the bulkhead line, and the tail-tower on the concrete barge.



Barge and Tail Tower for Building Foundations.

The concrete barge, about 30 feet wide and 100 feet long, was arranged as shown in the general plan. Near the shore end was a tower about 25 feet high which extended across the full width of the barge and contained two 1-yard cubical concrete mixers driven by an independent steam engine. The tower was three stories high with the concrete mixers set in the second story and discharging into special 1-yard steel dump buckets set on flat cars on the deck in the first story. The tower had four corner posts extending about 10 feet above the top of the third floor and two intermediate posts on each long side. On the shore side the intermediate posts extended up to the cap across the corner posts, on which were seated the ends of two horizontal trolley tracks. These tracks extended over the mixer hoppers and the measuring platform, and were supported at the opposite ends on the tail-tower of the cableway.

The tail-tower had a vertical mast with inclined longitudinal and transverse braces and wire rope guys to the corners of the barge. Between these braces was built a house for a 4-

drum Lidgerwood hoisting engine which operated the trolley hoists and two boom derricks, one on each rear corner of the tower.

Cement was stored on deck in the rear of the engine house and carried up inclines to the measuring platform. There were two wells in the measuring platform, and in each of them was set a 1-yard steel bucket with an eccentric bail latched in a vertical position. A steel bucket on castors was filled with sand from the deck of a barge moored alongside and was delivered to the measuring platform by one of the boom derricks and its contents dumped in the large bucket; then the requisite number of bags of cement were poured in on top of the sand and top of that was dumped a bucket of broken stone delivered by the other derrick boom from the barge on the opposite side.

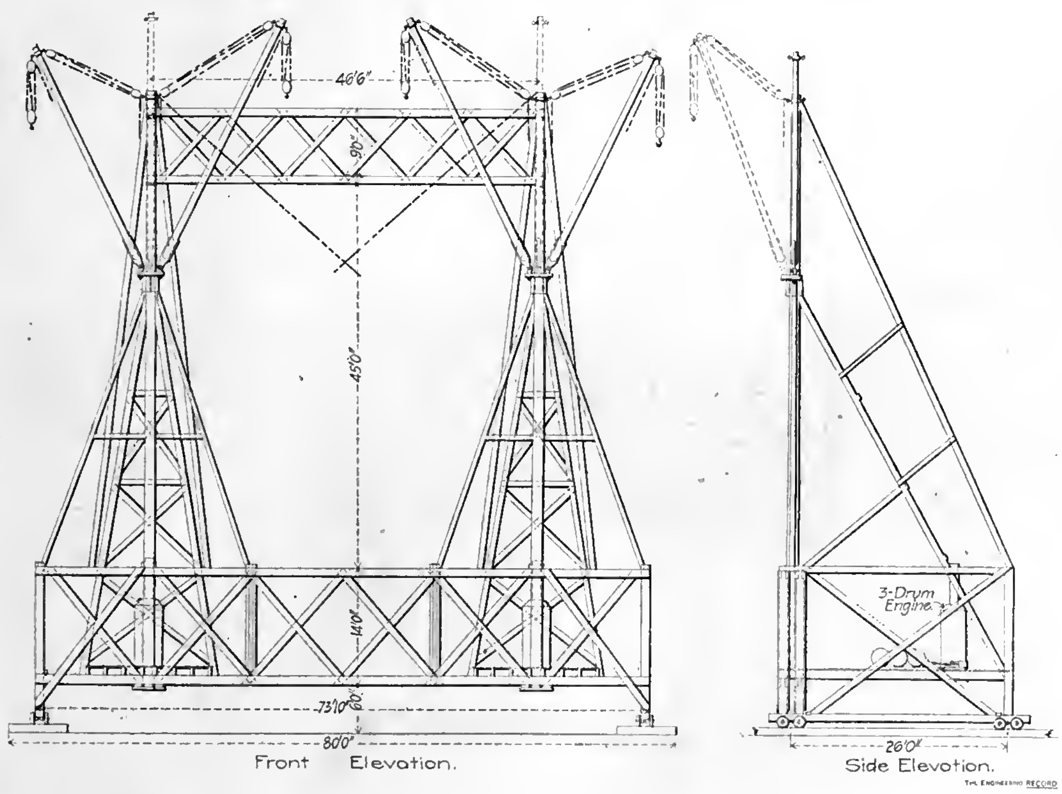
The bucket was then hoisted out of the well by the trolley hoist, which carried it over the upper platform of the tower, where it was dumped into the mixer hopper by releasing the bail-latch, which allowed the unstable bucket to revolve bottom up around the bail pivots. The materials were discharged from the hopper through a slide valve into the mixer and river water was admitted from an elevated tank. The amount of water was observed through a gauge glass, controlled by a valve and introduced into the mixer through a hollow trunnion and an inside perforated pipe parallel with the axis of the mixer.

The concrete hoppers in the top of the tower are 4 feet square with vertical sides 2½ feet high and an inclined bottom 18 inches deep with a 12x12-inch hole in the vertical spout 9 inches long. It is closed by a horizontal 12x20x ⅝-inch steel plate sliding on two 1-inch horizontal guide rods to which it is attached by bent straps riveted to the under side of the plate and running free on the rods. The mixer discharged into a special automatic dumping bucket which was designed for this work by the contractors.

The ends of a horse-shoe-shaped track on the barge deck passed under the concrete mixers and across the plane of the cableway. The concrete bucket was set on a flat car which was pushed by hand to the center of the track and there lifted by the cableway hoist, which carried it out across the bulkhead wall and dumped it wherever required. While a bucket of concrete was being removed from one mixer, the other was being charged, so that the operation of the plant was continuous and the concrete was mixed as fast as it could be handled. The cableway was operated by an engine in the head-tower where there was a 40-foot boom derrick for handling the large rocks which were carefully bedded in the concrete masses. About thirty men were required to operate the barges, mixers and cableway.

The footings for the transverse walls and column rows in the bulkhead house were laid on top of piles cut off about 1 foot above mean low tide, and several hundred piles had been driven and about 500 yards of concrete laid when reports were received of the recent discovery of piles which had decayed between high and low water levels under similar conditions. It was decided to cut the pile tops down to 1 foot below low tide and deposit the concrete on top of and around the pile heads, and methods were considered for lowering the water below low-tide behind the sea wall so that the work could be done dry and at any stage of the tide.

Obviously the river water must be excluded by cofferdams and although the sea wall was not designed for such a purpose nor supposed to be absolutely water-tight, it had been very carefully constructed and it was thought it might serve for the river side of the cofferdam and that the attempt should be made to pump out behind it. If the leakage was found to be very large it was intended to add pumps to as great an extent as should prove economical, and if necessary to divide the area into smaller sections with short sea wall fronts by making additional transverse cofferdams reaching to the shore line. These methods were to be exhausted before attempting to construct new cofferdams on the river front. Accordingly two sheet-pile cross walls were made about 400 feet apart, at the extremities of the first section of the bulkhead building, and one 10-inch centrifugal pump between them proved able to remove the water down to the required level and to maintain it there without working all the time to its full capacity, although the maximum difference of head inside and outside the cofferdam was 8 feet. The old concrete was blasted out, the piles cut down and the remainder of the site excavated to the required level and the foundations built there on the revised plan.



Traveler for Erecting Pier-Sheds.

The submerged part of the sea wall consists of a caisson 22 feet high with solid timber walls and filled with concrete. This rests on a 2-foot solid timber grillage on piles driven through 10 to 20 feet of cobblestones which had been deposited in a trench dredged 60 feet wide to hard clean bottom. Gravel was filled in around the pile tops and up to the grillage, and after the caissons were sunk was farther compacted by a quadruple row of piles driven close to the inside of the caisson. The transverse wall cofferdams were single rows of 10x12-inch yellow pine sheet piles grooved on each of the 10-inch faces to receive 2x4-inch spruce splines which were spiked to one pile before driving. Guide piles 8 feet apart, in two rows about 18 inches apart in the clear were first driven parallel to the center line of the cofferdam and two horizontal waling pieces were gained into the inside of each row, about 4 feet apart vertically. The planed inner faces of the waling pieces were 10 inches apart so as to fit snug against the sheet piles and the latter were driven with beveled lower ends so as to draw up close to the previously driven ones. Cross pieces were set against the guide piles on top of the waling pieces, packing blocks were wedged up between them and the piles as the latter were driven to keep them snug in line, and by these means the wall was made so tight that scarcely any leaks were developed when the water was pumped out.

The work was designed, as before stated, in the office of Mr. W. F. Whittemore, chief engineer of the North German Lloyd Steamship Company, and is being executed under his supervision. Messrs. R. P. & J. H. Staats are the general contractors for both substructures and superstructures. The Pennsylvania Steel Company furnished the structural steel for the three pier sheds and the American Bridge Company will furnish that for the bulkhead house, the erection of which has just been commenced.

An Electrically Operated Pumping Plant at Whitehall, Ill., belonging to the town, but operated by a private electric company, is located about a mile from the central station and provided with a number of special fittings which render an attendant unnecessary. Single-phase 220-volt current is delivered at the pumping station to a 25-kilowatt transformer which reduces the voltage to 208 volts for a 25-horsepower Wagner motor. This is geared to a Smith-Vaile triplex pump having a capacity of 15,000 gallons per hour. Oil is furnished to those bearings not fitted with ring lubricators by means of tubes running from the top of a cylinder placed horizontally over the top of the pump. Inside the cylinder there is a rod revolved by a sewing machine belt from the main shaft of the pump. This rod has a number of projecting arms tipped with wicking, which pick up oil from the bottom of the cylinder and press it into the ends of the tubes. In order to start the machinery, the brushes of the special starting commutator of the motor are fitted with a device for operating a hydraulic by-pass valve. When the machinery is started this valve is opened automatically and allows the water passing the pumps to flow directly back to the reservoir without subjecting the plant to any appreciable load. As soon as the motor comes to speed, the same motion of the brushes that throws the starting commutator out of service allows the hydraulic valve to close gradually and thus turn the pump discharge into the force main. This plant was recently described in the "American Electrician."

Moving a Long Railroad Bridge at New Brunswick, N. J.

The main line of the Pennsylvania Railroad crosses the Raritan River and the Delaware and Raritan Canal at New Brunswick, N. J., on a six-span steel bridge supported by masonry piers in the river and canal, and by abutments on either bank. The New York Division, on which this bridge, No. 26, is located, has now only two tracks at this point, but the plans for elevation of tracks through New Brunswick, now being carried out, contemplate the erection of a four-track arch masonry bridge to replace the present steel structure, and at an elevation which will raise the line about 14½ feet.

The center line of the new masonry bridge coincides with that of the present steel structure, and in order to proceed with the work, and at the same time provide for movement of the regular traffic, it was decided to move the present bridge 14½ feet south, to build the northerly half of the new bridge and then transfer to it the two main running tracks, after which the steel bridge could be taken down and the southerly half of the new bridge built.

Five of the spans, those over the river, were deck Pratt trusses, built by the Pencoyd Iron Works in 1895, each measuring about 150 feet in length and weighing, inclusive of track, 329 short tons, while the sixth span, over the canal, and to the west of the river, was a deck plate girder built by the New Jersey Steel & Iron Company, in 1898, measuring about 150 feet in length and weighing inclusive of track and draw center, 412 tons, making the total length of bridge to be moved about 900 feet and the weight 2,057 tons. The fixed spans were made up of two trusses under each track braced together and supported by pedestals engaging the end lower chord pins, making eight bearings on each pier, and four on each abutment. The distance from base of rail to bridge seat was 21 feet, and from bridge seat to high water about 22 feet additional. The problem was to move the 900 feet of bridge bodily southward 14½ feet, and the time allowed was thirty minutes, which was to cover disconnecting and connecting track, and changing signals. The date fixed upon for the work was Sunday, May 25.

Tracks were laid on each shore to connect with the new location of the bridge, this involving the erection of a trestle some 600 feet in length, and from 18 to 30 feet in height, on the westerly bank, and extensive changes in the platforms, shelters, etc., at the New Brunswick passenger station, about 850 feet west of the bridge. The southerly ends of the piers and abutments were prepared to receive the superstructure when the same should be moved, and on Wednesday, May 21, the canal was closed to the navigation of all vessels requiring more than 33 feet headroom.

The entire bridge was jacked up 4 inches, the bearing plates removed, and three standard 85-pound steel rails, or pieces of bar steel, were laid longitudinally on top of the piers under each transverse set of four pedestals. On each set of rails or bar steel were then placed nests of sixty or more steel rollers, the rollers measuring 1½ inches in diameter and 30 inches in length, spaced 6 inches center to center, the axis of the rollers being at right angles to the long axis of the pier. Flat steel shoe plates 2 feet in length, with the forward end curved slightly upward were placed on the rollers and under each pedestal, after which the bridge was lowered to a firm bearing. On the center pier of the drawspan a similar method was followed except that larger rollers were used.

The drawspan after being put out of service for canal navigation was rigidly fastened to the fixed span adjacent to it on the east. The use of the rollers, rails and shoes was merely to bring the dead weight of the bridge into a shape for easy handling and had nothing to do with the application of the power.

A hoisting engine was erected on a platform built at the foot of each river pier to the south, also at each end of the fixed spans and at the center fender pier of the drawspan, the level of the platforms being only 2 feet above the water. The engines were securely braced against the southerly faces of the piers. Seven engines in all were used, varying according to their position from 14 to 25 nominal horse-power, each engine having at least two spools.

Six long 12x12-inch timbers were anchored against the southerly face of each pier, extending from the river bed to about five feet above the top of the coping, and across the top of these was bolted a heavy crosspiece. From the crosspiece eight-part tackles were run to the southerly trusses under the north track, where the other end of the tackle was fastened to a timber connecting the end posts of adjacent spans. One eight-part tackle was furnished for the end posts of adjacent spans and also between the trusses under the north track and those under the south. The initial strain came on the trusses under the north track, which as they moved southward pushed the trusses under the south track before them, while any exceptional resistance to moving on the part of the south trusses would be immediately overcome by a strain on the equalizer block, which latter served also to secure uniform tension and operation of both sets of blocks and falls, and consequent uniform movement of the adjacent span ends. Stop blocks were set to a measurement of 14½ feet.

As the track on the bridge was not broken between the several spans, and was to be immediately used on the new line, and also in order to avoid any straining of the superstructure, it was essential that the bridge should be kept in good line during the moving, that is, for the entire length of 900 feet the movement should be uniform at every part. To gain this end a wire was led from a point on the superstructure opposite each place where the power was to

MOVING THE PENNSYLVANIA RAILROAD BRIDGE AT NEW BRUNSWICK.

each nest of rollers, i. e., one for each transverse set of pedestals. An equalizer, consisting of two fixed sheaves in a heavy piece of timber was rigidly fixed to the adjacent ends of the northerly trusses under the south track at each pier, the two sheaves being so spaced as to bring one over each of the roller nests on the pier.

One continuous 1½-inch manila line was carried from the engine to the south face of the pier, through single direction sheaves up the face of same to the eight-part tackle on one side, thence through the corresponding sheave of the equalizer to the equalizer sheave on the opposite side of the pier, thence through the other eight-part tackle, down the face of the pier by another set of direction blocks across the platform to the engine. The two ends of the line were then attached to separate spools on the engine.

In order to hold the trusses in the same relative position when the strain was put on the tackle, blocking pieces were inserted between be applied, to the pier or abutment below, around a sheave and along the bridge to a large tell-tale frame at the center span. The frame was hung out over the river and the wires connected to boxes strung vertically on the same. The boxes were then numbered to correspond with numbered indicator boards fixed to the bridge opposite each engine. Before the movement started all boxes were at the foot of the tell-tale frame, and as the bridge moved over to its new location they gradually rose. So all that an engineman had to do, was to have his engine running fast enough to keep his particular box even with the others, and from an indicator board on the tell-tale frame itself, he could also tell how far his portion of bridge had moved.

All preparations were completed at the time decided upon, the connections with the shore rails were cut, the last train left the bridge at 12.10 P. M., and at 12.12.03 one whistle was blown as a signal for the hoisting engines to take up the slack on the tackles. At 12.13.30 two whistles signalled the engines to go ahead, and as steam was put on the bridge moved south, while the tell-tale boxes began to ascend. White flags were waved from each pier to indicate that all was working smoothly, and the tell-tales moved upward evenly and uniformly. The west end of the bridge reached the required position, 14½ feet from the starting point, at 12.15.13 P. M., and the east end at 12.16.20, making the actual time of the operation two minutes and fifty seconds.

At 12.25 report was made that the track was in service and at 12.44 P. M. the first train crossed the bridge in its new location.

In the preparation of the work, the draw span had been set in its closed position, but it was swung open and ready for the passage of boats at 4.45 P. M. An inspection of the superstructure immediately after moving showed that none of the members had been in way strained.

The work was executed by the employees of the Pennsylvania Railroad Company and was planned and directed by the engineering department, Mr. W. H. Brown, chief engineer; Mr. W. A. Pratt, engineer of bridges; Mr. L. H. Barker, principal assistant engineer; Mr. F. P. Abercrombie, superintendent of the New York division, and Mr. A. M. Parker, supervisor of the local section. Master Carpenter G. W. Mershon and his assistant, W. R. M. Mershon, were in direct charge of the moving.

For several years bridge spans have been moved bodily in a transverse direction by American engineers to facilitate their replacement, as has been described in The Engineering Record in several cases, including the five-span Fort Wayne bridge, Pittsburg, which was illustrated in the issue of May 31. Recently it appears that this method has been used abroad, and one of the last issues of the "Engineer" describes the much slower and comparatively more costly operation of moving a single-span railroad bridge near London. An old bridge over a highway was to be replaced by a longer skew through plate girder span with a solid steel trough floor weighing over 100 tons. This was built on a falsework alongside of the old bridge and extending under and beyond it. Each bridge was jacked up and set on four 25-ton hydraulic rams with 18-inch stroke. Each ram was seated in a special heavy steel four-wheel truck, and a double acting pump was provided for each pair of rams. The track was disconnected at 2:25 A. M. Sunday morning, at 3:25 the spans had been successively moved to the new positions by hand windlasses, so that the new one occupied the former position of the old one which was displaced, and at 5 A. M. train service was resumed over the bridge. This shows an interruption of service of 2½ hours to move one 50-foot 100-ton girder span, while at New Brunswick a five-span 2,000-ton trussed structure 900 feet long was moved with a 34-minute interruption to traffic.

The Coke Oven Blowers in the Buffalo plant of the Lackawanna Iron & Steel Company are to be operated by direct-connected 75-horse-power Westinghouse induction electric motors. Four induction motors of 100 horse-power each will be used for operating the gas cleaning plant and the machine shop will likewise be driven by induction motors.

The Portland Cement Industry in the United States in 1901 is reported by the U. S. Geological Survey to have turned out a little over 12,710,000 barrels, an increase of about 4,230,000 barrels over the product of 1900. The imports during 1901 were a little under 940,000 barrels. The production of natural cement in 1901 was about 7,850,000 barrels, and the output of slag cement was about 273,000 barrels.

Underpinning a Tall and Narrow Brick Building.

The method of underpinning the south wall of the main part of the Decker Building, on Union Square, New York, was described in The Engineering Record of May 10, and affords an illustration of one of the tallest and heaviest walls ever supported on needlebeams while long sections of its foundations were removed. More than 2,000 tons of the lofty structure were supported on double tiers of long span steel beams several feet above the excavation, where pits had been dug in sand for adjacent new footings. Although this work was of considerable interest and much importance it conformed to ordinary conditions in that the wall underpinned formed one integral side of a large building with sufficient width to afford abundant transverse stability. It was also thoroughly braced and tied to the rest of the structure by the iron columns and floorbeams which were built into it and bonded it securely with the main framework.

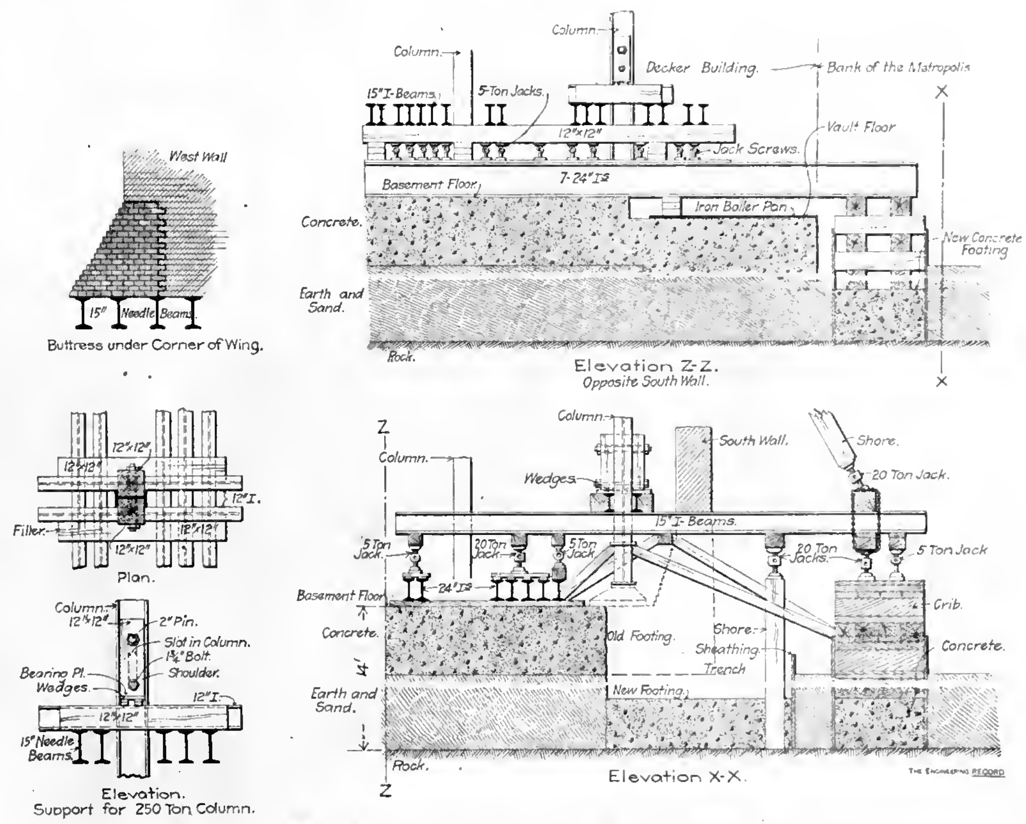
At the west end of the Decker Building there is a full-height 6x12-foot rear wing or extension, the foundations of which were on the surface several feet above the floor of the adjacent new cellar and some of which required to be extended down to rock, like those previously described for the south wall. The wing resembles a narrow tower, 175 feet high, which is structurally independent of the main building except for the continuity of the brickwork in the south wall, which extends from the main building to the outer corner of the tower, and for such bonding as is secured by the intersection of the north wall of the wing with the west wall of the main building. The walls are weakened by numerous windows and have built into their thicknesses four I-shaped cast-iron columns, which carry the floors. One of the columns has an estimated load of 600 tons and the loads on the others vary from 200 to 250 tons.

In one corner of the wing there is a square brick chimney weighing 200 tons, and as the walls are estimated to weigh 38 tons per lineal foot, the total estimated weight of the wing is about 2,500 tons, which was originally carried on a solid bed of concrete 4 feet thick, continuous over the full area of the wing.

The boilers and machinery for the freight elevator were located in the basement of the wing and in an outside vault at about the same level beyond its west wall, under the open court and alley. The elevator shaft extends up to the top of the wing and the rest of the space there is occupied by toilet rooms.

On the south side a new footing is being carried down to rock adjacent to that for the Bank of the Metropolis. It will act as a retaining wall for the sand under the basement floor of the wing, and the other footings on the 4-foot basement floor will not be underpinned.

The drain and sewer pipes were removed from the basement floor and either cut off and capped, or suspended from the ceiling and arranged to temporarily discharge into special connections with the street sewer. The freight elevator service was restricted to the upper stories, and the guides removed in the basement to give more working space there. The elevator ropes were disconnected from their hoists, led around guide sheaves, across the Bank of the Metropolis site and under the sidewalk to the drum of a hoisting engine which, with steam boilers, was set in Sixteenth street. The changes were effected at night without interrupting the elevator service.

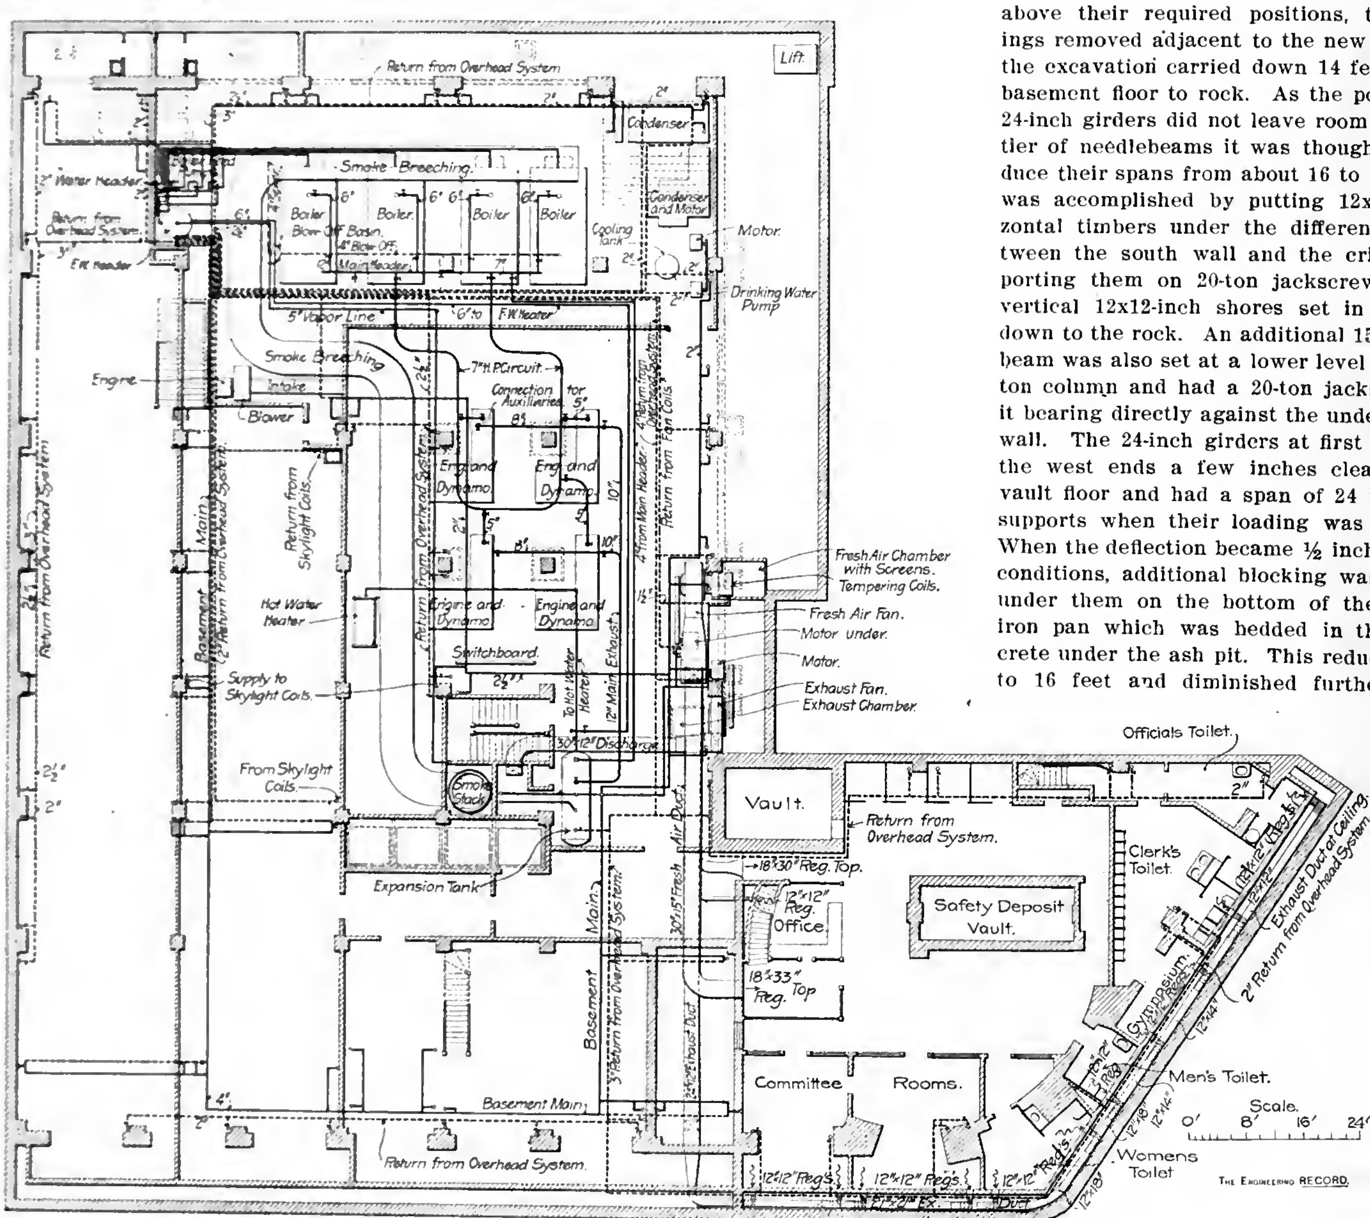


SUPPORT OF WALLS, COLUMNS AND CHIMNEY IN NARROW EXTENSION.

On the south side of the wing sheeted pits were dug in the site of the Bank of the Metropolis, and in them 7x7-foot concrete footings were built on the rock and supported solid timber cribbing which was carried up several feet above the bottom of the general excavation. Four lines of 12x12-inch continuous stringers were laid across the tops of the cribs and bridged from one to the other parallel to the south wall. Each pair of stringers was capped with transverse planks on which jackscrews were seated with their lower ends projecting down between the stringers. The jackscrews in the row nearest the wall were each of 20 tons capacity and those in the outer row were of 5 tons capacity. On each row of jackscrews was seated a 12x12-inch longitudinal distributing girder which carried the south ends of the sixteen 15-inch needlebeams 28 feet long. These supported the brickwork and columns and were arranged and inserted about as explained in the previous description of the main wall underpinning. These beams were, however, in one tier instead of two, and their north ends were supported on longitudinal girders instead of on cribs and piers.

Seven 24-inch 100-pound steel I-beams, 30 feet long, were laid parallel to the south wall on the 4-foot concrete floor. Their west ends projected through the vault and a few feet beyond the north and south line of the bank lot, and were carried on timber cribbing about 8 feet high, built on a concrete pier footing which had been carried down to bed rock for the bank building. Six of the girders supported two lines of 5 and 20-ton jackscrews, which carried the north ends of the needlebeams on 12x12-inch longitudinal timbers the same as at the south end. The seventh girder carried a single line of 5-ton jackscrews near the north side of the south wall.

The weight of the brick wall and chimney was transferred to the needlebeams as described in the previous article. The south wall column with a floor load of 650 tons was built into the brickwork, filling the spaces between its transverse web and the flanges which are in the faces of the wall. The brickwork is of excellent quality, well bonded and has bearing against the under sides of the horizontal diaphragms which unite the flanges and web at frequent intervals, and against the column-splice flanges at every story. It was therefore assumed that the brickwork would safely carry the column, and the latter was not directly connected to the needlebeams, seven of which were set close to it under the wall.



Mechanical Plant of the First National Bank Building, Uniontown, Pa.

Two of the needlebeams were set just outside the west wall and supported it at the corner by a brick buttress built across their top flanges and gained into the old brickwork. Underneath the chimney the needlebeams were reinforced by timber A-braces reaching from the middle of the lower flange, where they had beveled ends abutting on the vertical sides of a short transverse timber. The lower end of one brace was fitted to the bottom flange and web of the nearest 24-inch girder and the lower end of the other brace was fitted to the tops of the sheeting in the pier under the south ends of the needlebeams. The webs of the 24-inch girders were blocked solid to resist the thrust from one diagonal brace and a horizontal strut was braced against the opposite side of the pier to resist the transverse component of the thrust from the other brace.

One of the interior columns, with a 250-ton load, had vertical timber shoulders or bearing pieces fitted against the web between the flanges on both sides and clamped together by a ¾-inch bolt at the bottom and a 2-inch steel pin through the top. The latter had a horizontal bearing in the upper end of a vertical slot cast in the web of the column. Thin steel wedges were driven under the lower ends of these shoulders and transferred the column load to the I-beams and filler timbers which were set across the needlebeams on both sides of and close to the column. The lower end of the column projected below the needle beams and was securely braced by inclined struts wedged against one of the horizontal diaphragms cast on the column. Their lower ends were secured in the same manner as those of the needlebeam struts.

A longitudinal timber was chained to the needlebeams and one of the jackscrew stringers as described in the former article. Beveled seats were gained into it to receive two 20-ton jackscrews at the feet of long inclined shores which braced the outside of the south wall at the second story. At this point an offset in the brickwork projected 6 inches and afforded a horizontal bearing against which a timber 3 feet long was set to form an angle block distributing the pressure of the shore on the brickwork so as to avoid danger of crushing it.

The walls and columns were lifted ⅛ inch above their required positions, the old footings removed adjacent to the new building and the excavation carried down 14 feet below the basement floor to rock. As the position of the 24-inch girders did not leave room for a double tier of needlebeams it was thought best to reduce their spans from about 16 to 12 feet. This was accomplished by putting 12x12-inch horizontal timbers under the different groups between the south wall and the cribs, and supporting them on 20-ton jackscrews on top of vertical 12x12-inch shores set in pits carried down to the rock. An additional 15-inch needlebeam was also set at a lower level near the 650-ton column and had a 20-ton jackscrew set on it bearing directly against the under side of the wall. The 24-inch girders at first projected at the west ends a few inches clear above the vault floor and had a span of 24 feet between supports when their loading was commenced. When the deflection became ½ inch under these conditions, additional blocking was wedged up under them on the bottom of the thick cast-iron pan which was bedded in the floor concrete under the ash pit. This reduced the span to 16 feet and diminished further deflection while still transmitting part of the 500-ton total load from the needlebeams to the rock foundation at the west ends of the girders.

The underpinning is in charge of Mr. A. E. Riendeau, who has designed and supervised it for the George A. Fuller Company; Mr. C. T. Purdy, chief engineer, contractors for the Bank of the Metropolis.

Wringing Blue-prints in the same way that clothes are passed through a wringer in a laundry has proved so satisfactory that a special machine for the purpose has been designed by the American Wringer Company, 99 Chambers Street, New York. It is made in several sizes to take prints from 12 to 30 inches wide, and has helical steel springs to press the rolls firmly together.

The Mechanical Plant in the First National Bank, Uniontown, Pa.

The First National Bank, of Uniontown, Pa., has just completed the largest building of that industrial city, for its own use and for the rental of offices. Exclusive of basement and attic, the building is 11 stories high, occupying an irregular space of approximately 10,100 square feet between Main, Pittsburg and Peters Streets, and is of the steel-cage type of construction. It is fitted with electric light and telephone services, mail chutes, ice water distribution, and a heating and ventilating system supplied from its own steam plant in the basement. Plans of the latter as well as of the attic and one of the intermediate floors is herewith shown.

The steam plant includes four horizontal tubular boilers, made by Heggie Brothers, of Joliet, Ill., in which steam is generated at a working pressure of 125 pounds per square inch. Each boiler has a heating surface of 1,070 square feet and is fitted with Jones underfeed automatic stokers made by the Underfeed Stoker Company of Chicago. The furnaces are operated under forced draft from a blower nearby taking air from the engine room, thereby ventilating the latter.

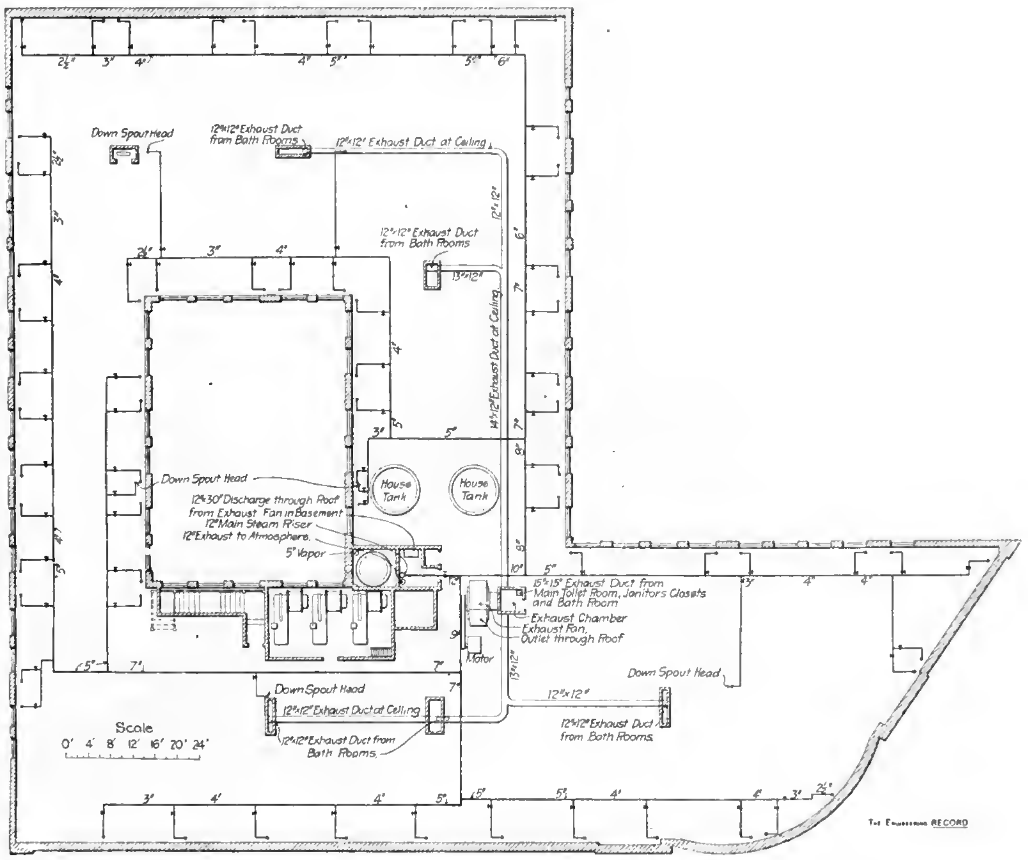
Steam is taken from the top of the boilers through 6-inch outlets and flows into a 12-inch horizontal header over the rear of the boilers. From the header are taken two 7-inch branch mains which are connected at their far ends to form a ring main or loop for the supply of four generating sets, grouped in a rectangle.

The boiler water supply is principally obtained from the returns of the heating system which, coming from the foot of the risers, drains by gravity into a 700-horse-power open feed water heater manufactured by Warren Webster & Company, of Camden, N. J., in the boiler room. This, in addition to utilizing exhaust steam to heat the water, is used to perform the offices of a feed-water purifier and of a return tank for the reception of the return water, and the automatic control of the feed pumps. Passing into the heater it is drawn off by 6x4x6-inch pumps installed in triplicate, made by the Laidlaw-Dunn-Gordon Company, and discharged into a 3-inch header. The header is located against the boiler room wall at the pumps, and affords very convenient means of control, the feed line to each boiler leaving it separately. It was deemed advisable to locate the boilers in the rear for readily receiving their coal supply, notwithstanding the previous location of the stack behind the elevator shafts; this has necessitated a long smoke connection in the basement from boilers to stack as shown. Coal is taken from a vault in front of the boilers.

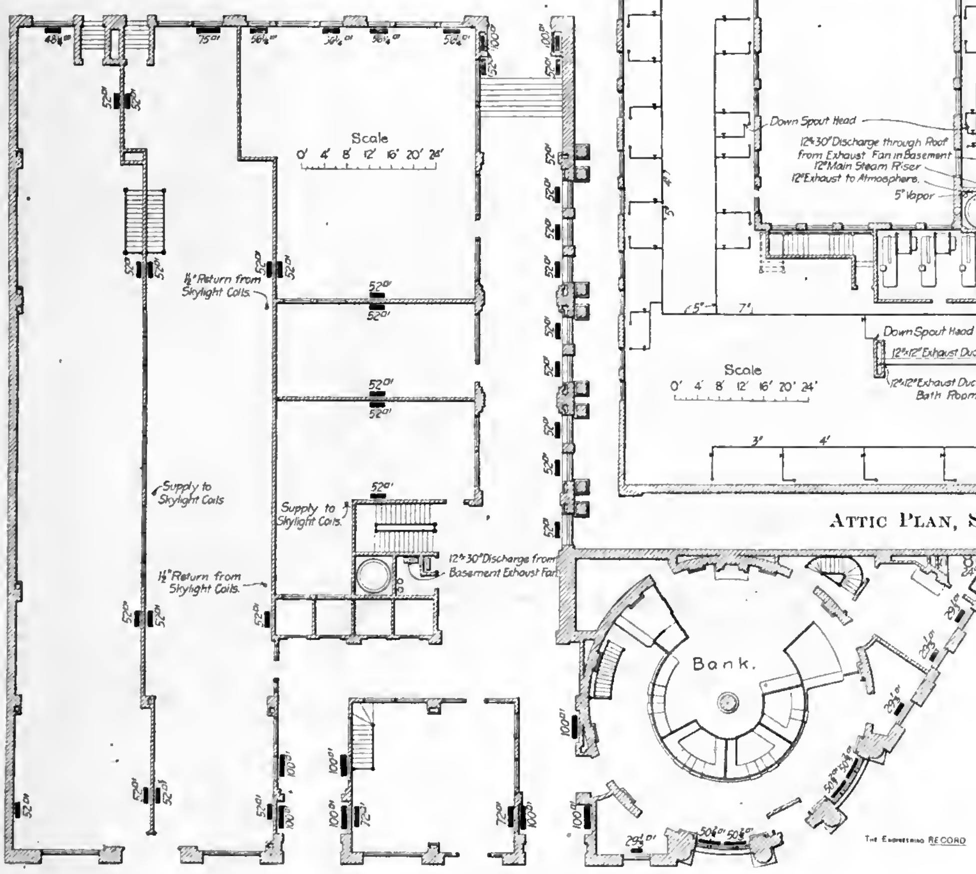
The engines are horizontal tandem compound engines made by the Ball Engine Company. Each is 12x19x14 inches in size and operates at 250 revolutions per minute; the 100-kilowatt Crocker-Wheeler dynamos to which they are coupled generate current at a potential of 125 volts. The engines are fed with steam, as mentioned, from a 7-inch loop overhead and exhaust into 8-inch lines joining a 10-inch main which runs to an expansion tank, 12 feet long by 4 feet in diameter. This tank serves as a low-pressure steam receptacle from which there may be an equalized pressure of steam on all the lines leading from it. Assuming three of the four engines exhausting at the same time, 2,500 cubic feet of steam will be delivered to the expansion tank per minute, irrespective of steam pressure. This means that the tank will be filled 16 or 17 times in that time, and will to that extent act as a muffler in reducing steam pulsations and resultant vibrations, as well as equalizing the pressure in the outgoing lines from the pumps. Besides being supplied by the exhaust mains, a 4-inch live steam branch is led into it, which allows the steam-heating apparatus to work under a wider limit of pressure and temperature. The following connections are made independently with the tank; a heating main for the basement, including the fan coils, the heating main from the rest of the building, the free-exhaust riser, a main for warming some adjacent buildings and a main sub-divided for the feed-water heater, and a hot water heater for the house supply.

The ventilating apparatus includes two basement steel plate centrifugal fans of the American Blower Company's manufacture, one for exhaust ventilation of the safe deposit vaults in the basement and the other for the supply of fresh air to the same. An attic fan draws from an exhaust chamber into which two flues deliver vitiated air from the toilet rooms throughout the structure. The supply fan is 48 inches in diameter, 14 inches wide and is intended to deliver 3,000 cubic feet of air per minute against a pressure of 0.09 ounce per square inch. It takes air from a screened fresh air chamber, as shown, and drives it out over a heating surface of 445 square feet into a 30x15-inch galvanized-iron duct to two registers at the ceiling in the vault room. The drawing shows the manner in which the ends are expanded to reduce the velocity of the air flow. The discharge fan draws from an exhaust chamber 4x4 feet in plan, to which is brought a main 12x12-inch duct from several registers on the sidewalls of the smaller rooms, as shown. The discharge from the exhaust fan is carried over to a vertical flue, whence it makes its exit through the roof.

The heating of the building is accomplished by direct means, with the exception of the small amount of indirect already mentioned. For the greater part, the overhead method of distribution was adopted and a 12-inch steam supply riser carried from a connection on the expansion tank upward to the attic, there feed-



ATTIC PLAN, SHOWING THE OVERHEAD HEATING PIPING.



PLAN OF THE FIRST FLOOR.

ing into a 10-inch distributing main. From the latter are taken off various branches to 65 downward lines of pipe at the outside walls of the building, connecting with the numerous radiators. The radiators have one-pipe connections and the steam condensation drains from the drop lines, as before mentioned, into the basement return mains. The overhead system supplies the radiators of the second to eleventh floors inclusive. The return mains from the bottom of drop lines are run in the basement in trenches, and are pitched to drain into the feed-water heater. The basement heating mains also supply one-pipe radiators and are graded downward in the direction of steam flow to cause water of condensation to pass with the steam, in turn to be discharged into the return mains. The basement system includes first-floor radiators and skylight coils in the second story, comprising altogether about 3,370 square feet of radiation. The overhead system feeds about 20,075 square feet, making a total surface of direct in the building 23,445 square feet.

The lighting system of the structure is quite extensive. Current from the generators is distributed by two-wire feeders to panel boards. Feeders from the latter are tapped in the usual way. There are two general centers for this distribution, with an adjacent riser shaft in each case. Each riser shaft contains one main feeder which supplies current to that part of the building through which it is run. Provision for an equal division of the total load has been made by connecting the several main feeders, in their various positions, to the middle of branch circuits between the second and eleventh floors inclusive. One feeder supplies the lights on the first floor and store rooms in the basement. The switchboard, located in the basement, contains the usual panels for the separate control and supervision of each generator and feeder panels, one switch per feeder. Current is also taken for the operating machinery of four elevators and for the motors of a refrigerating plant.

The refrigerating plant, made by the Carbondale Machine Company, of Carbondale, Pa., is run on the compression system. The compressor operates through belting from a 40-horse-power motor. The plant is installed to furnish cold drinking water for the employees and tenants, and is circulated by a 6x4x6-inch pump, also motor-driven. The ammonia gas is cooled through the agency of pipe condensers in the usual way, but artesian well water, not only being cheaper, but colder than the city supply in warm weather, is used as the cooling medium.

The elevator plant consists of three passenger elevators, one combination elevator and a sidewalk lift. They are of the electric drum type, the machines being located overhead, and were installed by the Otis Company, of New York. The motors are run under 110 volts and the cars are under magnetic control. The passenger elevators have a carrying capacity of 2,250 pounds and are designed to travel at the rate of 300 feet per minute. They operate between the first and eleventh floors inclusive. The freight elevators, traveling between the basement and the attic, have a lifting capacity of 4,000 pounds and a speed of 150 feet per minute, while the sidewalk lift carrying a maximum load of 2,500 pounds runs at 50 feet per minute.

The building was erected from the plans of Messrs. D. H. Burnham & Company, of Chicago, and the mechanical plant described was designed by Mr. C. M. Wilkes, their engineer. The heating and ventilating apparatus was installed by the L. H. Prentice Company, of Chicago, Ill., and the lighting plant by the Iron City Engineering Company, of Pittsburg, Pa.

Water Supply in the Carnegie Residence, New York.

The residence now being completed for Mr. Andrew Carnegie, on upper Fifth Avenue, New York, opposite Central Park, is a four-story and basement house about 70x130 feet in principal dimensions, besides conservatory and picture gallery extensions. It occupies a lot extending from 90th to 91st Streets and having a depth of about 225 feet east from Fifth Avenue, and is surrounded by a moat, lawns, flower gardens and shrubbery, laid out by a landscape architect, for which elaborate water supply and drainage systems have been installed in connection with those for the house service.

Except a 500-gallon attic tank which is installed to provide an auxiliary supply to supplement the regular service in case this should be interrupted, all the tanks, pumps, filters and other plant connected with the water supply and the whole installation for the water system, except the riser pipes for fixtures and their short branches, are located in the cellar, and the distribution pipes, connecting mains and other horizontal branches, are suspended from its ceiling. The filter plant and suction tanks occupy one room; the pumps are arranged in an adjacent room and the cold-water pressure tanks and hot-water heating tanks are arranged in a third room. These rooms are of sufficient size and height to prevent crowding, permit the advantageous arrangement of the plant, afford clearance around the tanks and other apparatus and space for their connections and to run the pipe lines, and are well lighted, neatly finished and have their walls faced with enameled white bricks. This rather unusual architectural provision for the plumbing installation promotes economy of construction and maintenance.

Water is provided for domestic purposes, for fire protection and for sprinkling and hose washing. In the cellar and basement it is normally under street pressure, and for the rest of the house it is under direct pump pressure, both systems, together with the auxiliary tank pressure being cross-connected so as to be interchangeable. Water for all purposes except irrigation and hose washing is normally filtered, storage, about 6,600 gallons, being provided by the suction, pressure and auxiliary attic tanks.

All water pipes are of drawn seamless brass, tinned inside and outside and tested in place by a water pressure of 150 pounds per square inch, applied after the lines are completed. All drain and leader pipes are of screw-jointed wrought iron or steel, specially galvanized for this order. Screw-jointed brass pipes with recessed brass drainage fittings are used throughout for all soilpipes and for waste and trap-vent lines, including short brass connections to fixtures. All exposed pipes are frost-proofed by a 1-inch packing of hair felt or asbestos, covered with canvas sewed on and painted. All gate valves are of steam metal made by the Chapman Valve Manufacturing Company and, except in the basement, are nickel plated. All fixtures have separate white metal gate-valves and air chambers, and all riser lines have air chambers and air valves at the top and controlling and emptying valves and waste pipes at the bottom. All valves have numbered brass tags corresponding to printed key-diagrams. All bathrooms and slop-sink closets have tiled floors laid in full-size safes made of 4-pound sheet lead turned up 3 inches on all sides and provided with a strainer outlet and waste pipe emptying through a brass flap-valve over a porcelain sink in the cellar. The refrigerator safes have convex strainers with trapped wastes supplied with hot water for flushing them out, and emptying through numbered flap valves into a cellar sink. The riser lines are mostly grouped together and carried up in furred spaces in the outside walls; there are no horizontal branches crossing any of the upper floors.

The water supply is distributed under three general systems, viz., street, pump and tank pressure, all of which are cross-connected so as to be interchangeable. The street pressure system is subdivided into unfiltered water for garden sprinkling and for washing out the fresh air inlet pipes, and filtered water for domestic purposes. The filtered water system is divided into hot and cold supplies for basement and cellar and refiltered cold water for drinking purposes. The pump pressure system is divided into filtered hot and cold water for domestic purposes and fire lines in the upper stories and refiltered drinking water for the upper stories.

Separate 2-inch taps are made in the street mains in 90th Street and in Fifth Avenue, and the supplies pass through 3-inch Trident water meters, valves and check valves, and are branched to the sill-cock distributing line, which also supplies the fresh air inlets at the main traps with unfiltered flushing water. Each of the two 2-inch street supply pipes has an attachment for preventing water hammer, and is connected to an improved double-cylinder Loomis filter of a capacity of 30 gallons a minute under 25 pounds pressure. The filter cylinders are about 3 feet in diameter and 6 feet high, set on brick piers; one is filled with quartz sand and the other with charcoal or sand and polarite. They have aerating apparatus but no alum attachments, and their filtering materials can be replaced through large manholes. They are valved and piped for washing and emptying and are cross-connected so that they can be used separately, alternately or together. One is normally used under street pressure to supply only the cellar and basement; the other, although operated under street pressure, is for the pump-pressure supply to the upper stories.

The pump-pressure filter normally discharges through a 2-inch pipe to two vertical closed 3½-foot cylindrical suction tanks, 12 feet high, with a capacity of 888 gallons each. The tanks are cross-connected and provided with manholes and emptying pipe; they are white enamel painted inside, and tested to an internal pressure of 50 pounds per square inch. The 2½-inch outlets are connected to two Quimby pumps, which discharge into two pressure tanks from which supplies are taken to all the hot and cold water fixtures in the upper stories. The arrangement of the meters, filters, suction tanks, pumps and pressure-tanks in duplicate and cross-connected throughout provides a complete reserve installation to maintain the supply if any part of the system should be disabled or out of service for alteration or repairs.

Provision is made for screwing outside 1-inch hose to the sill-cocks to spray the trees and shrubbery with unfiltered water direct from the street mains, and to secure a higher pressure than may be always available from the Croton system, it is proposed to install in the cellar a supplementary pump, not shown in the general plan. A branch from the 2-inch service pipe from the 5th Avenue main will deliver into a 40-gallon tinned copper boiler suspended horizontally from the cellar ceiling and having a 1½-inch outlet to a Quimby rotary house-service pump, driven by a direct-connected 2-horse-power electric motor. The pump will have a capacity of 15 gallons a minute at 40 pounds pressure, and will have a short rubber hose connection to a 1½-inch discharge pipe, on which there will be a Ford pressure regulator connected to an electric switch and adjusted so as to automatically start the pump whenever one of the sill-cocks is opened, and to stop it when the sill-cocks are all closed and the pressure rises to about the average street pressure. The pump will be cross-connected to the filtered water supply and can be used to increase the pressure in the cellar and basement fixtures.

The house-pressure pumps have extreme dimensions of 16x55x20 inches high, and are set in copper drip pans with 1 inch of hair felt cushion between the pan and the leveled surface of the masonry foundation. Each pump has short lengths of five-ply rubber pressure hose with tinned brass couplings on the inlet and outlet to secure noiseless operation, and is driven by an independent 3-horse-power compound-wound motor, manufactured by the General Electric Company. Each pump is guaranteed to deliver 1,800 gallons an hour against a head of 160 feet and is fitted with a Ford pressure regulator connected to an electric switch so as to automatically start and stop the pump when the pressure in the tank falls or rises below the required limit. The pumps are cross-

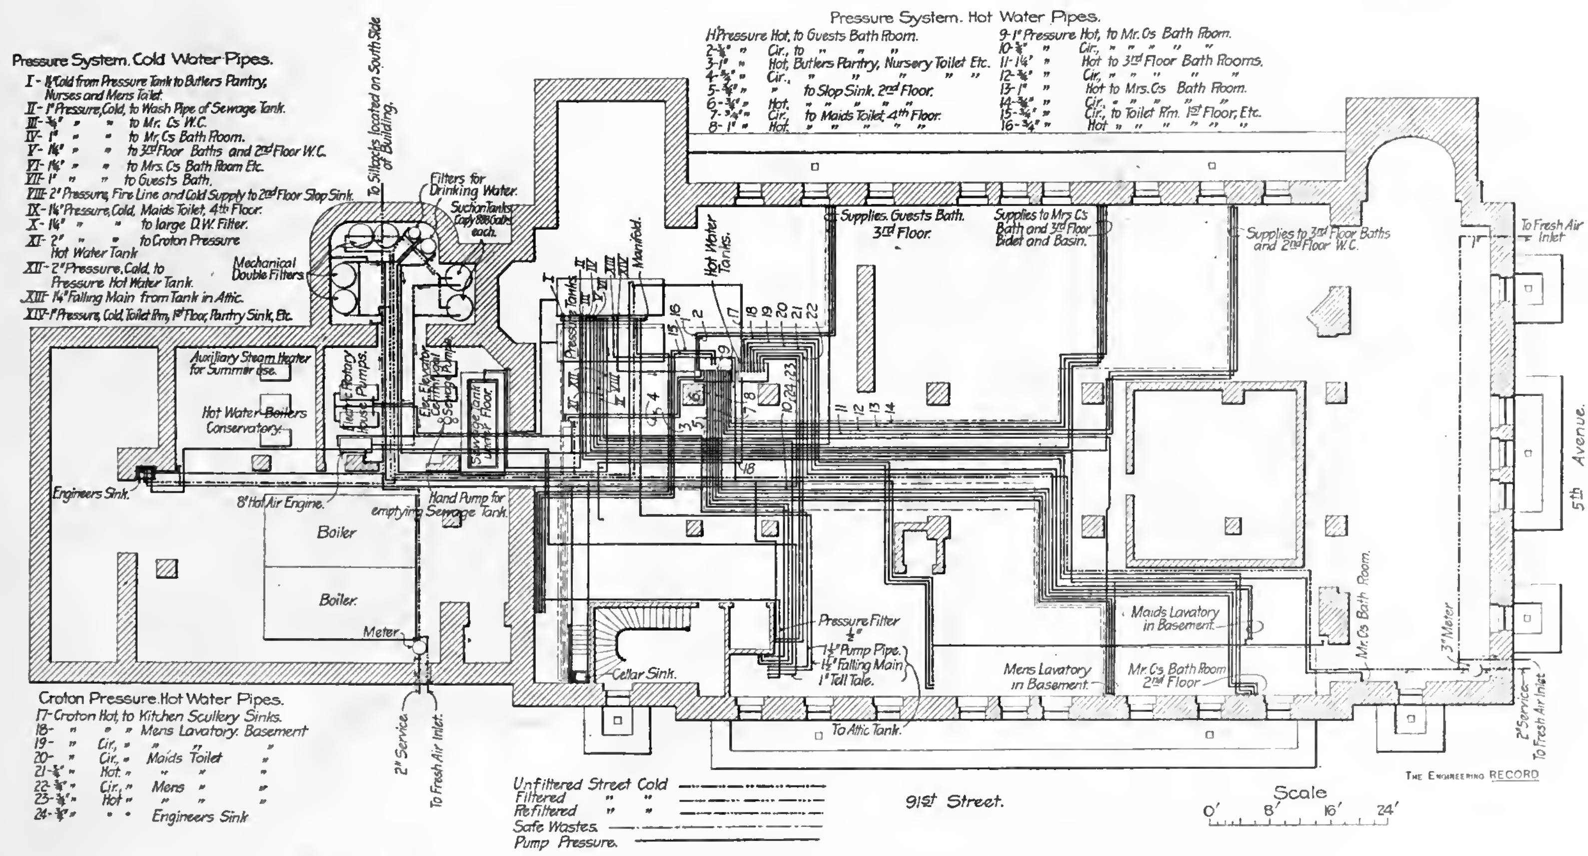
ply to the conservatory fountain and sink, and one 1½-inch, four 1¼-inch, four 1-inch and one ¾-inch lines.

In the cellar, suspended from the steel I-beams in the basement floor, are two horizontal cylindrical hot-water tanks, made of copper, polished outside, tinned inside, and tested for 150 pounds internal pressure. One tank is 30 inches in diameter and 4 feet long, has a capacity of 148 gallons, and is normally used under street pressure to supply cellar and basement fixtures. The other, 36 inches in diameter and 5 feet long, has a capacity of 265 gallons and normally supplies hot water under pump pressure to the fixtures in the upper stories. The tanks are cross-connected and each contains a coil of 1½-inch brass pipe proportioned to heat the water with steam at a pressure of 5 pounds. Both tanks are fitted with thermometers, gauges, safety and blow-off valves, emptying pipes and thermostats to automatically regulate the supply of steam to the heating coils and maintain the water at a constant temperature. They are covered with Keasbey's sectional magnesia and canvas sewed on and painted.

dry. These two tanks supply hot water to all fixtures in the house except the waterclosets.

In the house-supply filter room are two large Berkefeld supply filters for filtering the drinking water. Normally one is connected with the street pressure, and the other with the pump pressure filtered water supply, but they are cross-connected so that either can be put under either pressure or can be supplied with unfiltered water. One filter has twenty-one 15-inch cylinders 43 inches high and has a capacity of 10½ gallons per minute under 40 pounds pressure. It is connected with the street pressure system and supplies the basement fixtures through three pipes, a ¾-inch line to the kitchen and scullery sinks, a ½-inch line to the butler's pantry sinks, and a ½-inch line to the engineer's sink. The other filter has thirty 20-inch cylinders 43 inches high, with a capacity of 15½ gallons a minute under 40 pounds pressure. It was designed to supply upper-story bath rooms and toilet rooms through six ½-inch lines, but the plan has been revised so as to supply only a pantry and slop sinks through one rising line.

In order to provide a water supply for the



ARRANGEMENT OF WATER-SUPPLY PLANT AND DISTRIBUTION LINES IN BASEMENT.

connected at both suction and discharge ends, and have relief valves and emptying pipes which discharge into an underground tank.

The two pressure tanks are 5-foot horizontal cylinders 14½ feet long and hold 2,150 gallons each. They are made of boiler iron, painted with white enamel inside and also painted outside and tested to 150 pounds per square inch internal pressure. They are fitted with blow-off pipes, gauge glasses, and manholes, and are connected at the top by a valved equalizing air pipe. The 3-inch bottom outlets are valved to a horizontal distribution header between them, which is made up of 4-inch tinned brass nipples and tees and has connections to the supplies for the different lines of fixtures in the upper stories, and to the fire service, hot water service and drinking water filter. There are thirteen distribution branches from the header, each being valved and dripped. They include a 2-inch supply to the hot water tank, a 2-inch supply to the fire lines, a 1-inch sup-

The street pressure tank has two 2-inch outlets connected to a 2-inch header from which one ½-inch, three ¾-inch and two 1-inch pipes are taken to supply the different distribution lines. The pump pressure tank has two 3-inch outlets connected to a similar horizontal 3-inch header made up of tees and nipples and connected to two 1¼-inch, four 1-inch and two ¾-inch pipes to the distribution lines supplying the upper story bath and toilet rooms and slop-sinks. A return-circulation pipe is run separately from the highest fixture in each group and connected in the cellar with a manifold at the bottom of the tank. All flow and return risers have controlling and emptying valves at the hot water tanks. In winter the coils in the hot water tanks will be supplied with steam from the large house heating boilers; in summer they will be supplied with steam from a special smaller auxiliary boiler. There are no range boilers or waterbacks in the house and no boilers in the kitchen or laun-

upper story fixtures in case the pump pressure system should be disabled, a gravity supply from an attic tank is provided for auxiliary use. Water from the street main or the suction tanks is raised about 75 feet to the 750-gallon attic tank by an 8-inch Rider hot air engine in the cellar pump room. The engine has 1½-inch inlet and outlet pipes and a capacity of 2,000 gallons an hour under 50 feet head. It is provided with a coal furnace, a copper air chamber and an automatic cut-off arrangement to stop it when the house tank is filled up to the telltale. This pump and all other pumps are seated on brick piers faced with white enamelled bricks and having cut stone caps.

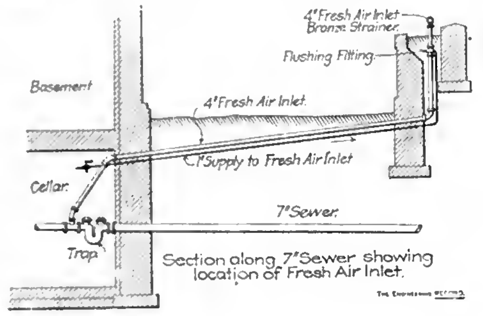
The 2x5x10-foot attic tank is made with 2x4-inch wooden staves laid flat, nailed together and dovetailed at the corners. It is lined with 16-ounce planished tinned copper, is seated on a platform supported on steel I-beams and covered with 4-pound sheet lead, turned up 3 inches on all sides, and has a tinned wooden cover, made in three sections. There is a 1½-inch emptying pipe to the roof gutter and a ¾-inch telltale 1 inch below the level of the 3-inch overflow pipe. There is a 1½-inch brass supply pipe from the bottom of the tank to the distribution header between the two pump pressure tanks. Normally the valve at the foot of this pipe is closed and all the other valves at the header are open, but if it is necessary to supply the house from the attic tank the foot valve is opened and the two valves on the pressure connection between the header and the pressure tanks are closed.

On each floor, including the cellar and attic, there is one hose reel, seven in all, with 125 feet of hose, nozzle coupling and gate valve complete for the fire protection service of the house. The hose is of unlined mildew-proof linen, warranted to stand a pressure of 400 pounds per square inch, and to be of make acceptable to the Board of Fire Underwriters. The 30-inch nozzles have swivel handles, and with the valves and couplings are nickel plated. The swinging hose reels are made of gun metal, nickel plated. It is specified that the hose, after having been wet and dried, shall not leak more than 1/6 gallon per foot in the first minute under a pressure of 75 pounds, or more than 0.01 gallon per foot in the second five minutes under a pressure of 75 pounds per square inch.

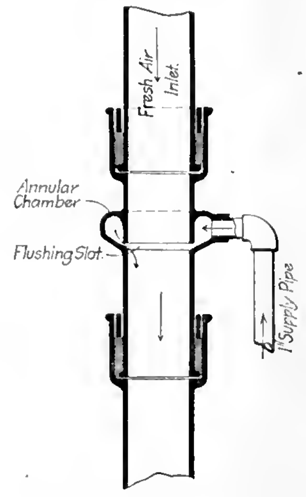
Each sewer trap is vented by a fresh air pipe pitched up about 1:6 from the cellar wall to the area wall and thence carried vertically to terminate with a bronze strainer above the surface of the ground. The upper section of the vertical pipe is about 3 feet long, and just below the surface of the ground is calked into the bell of a special fitting which, as shown in the general view and detail, is provided with a flushing arrangement designed to wash down all rust and accumulations of dust or rubbish into the sewer pipe. An annular chamber is cast around the outside of the pipe, and into it is tapped a 1-inch supply pipe from the street pressure system in the cellar. Just over the main trap this pipe has a stop and waste cock which allows the annular chamber to be filled and flush out the vertical pipe through a horizontal slot in its sides.

There are seven bath rooms for the family and guests and three for the servants, besides five toilet rooms without baths. The total number of fixtures includes eight wash-basins, ten servants' wash-basins, eight water-closets, seven servants' water-closets, seven bath-tubs, three servants' bath-tubs, three sitz baths, one shower, one shower and needle bath, one shampoo wash stand, four slop-sinks, three pantry sinks, three scullery and kitchen sinks, one still room sink, one brush-room sink, one conservatory sink, one engineers' sink, one refrigerator sink, one conservatory fountain, four laundry tubs, two kitchen ranges and three floor cesspools.

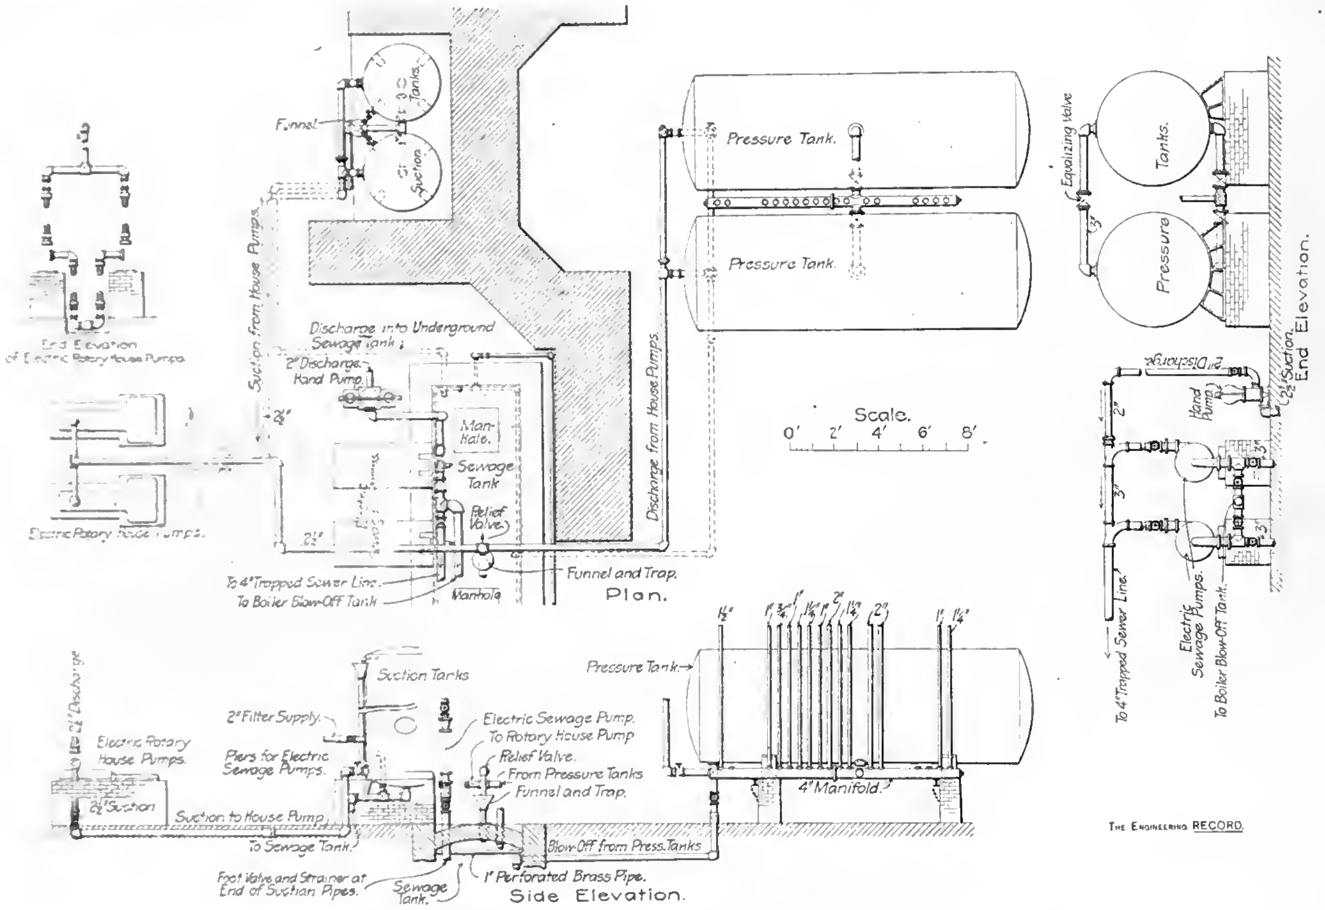
Messrs. Babb, Cook & Willard are the architects, and Mr. Wm. Paul Gerhard is the hydraulic and sanitary engineer of this residence. Mr. James Armstrong is the contractor for the plumbing and water supply system.



Section along 7" Sewer showing location of Fresh Air Inlet.



Flushing Fitting for Fresh Air Inlets.



Location and connection of Pumps and Tanks in Cellar.

DETAILS OF WATER SUPPLY IN THE CARNEGIE RESIDENCE.

A Steam Railway 40 miles long, the Cincinnati, Georgetown & Portsmouth Ry., is shortly to be converted from steam to electric traction. The Tennis Railway Equipment Co., which has the contract, has recently purchased from the Westinghouse Electric & Manufacturing Company two 600-kilowatt alternating-current generators and a number of 300-kilowatt rotary converters for supplying current to the line.

The Septic Tank System at Birmingham,

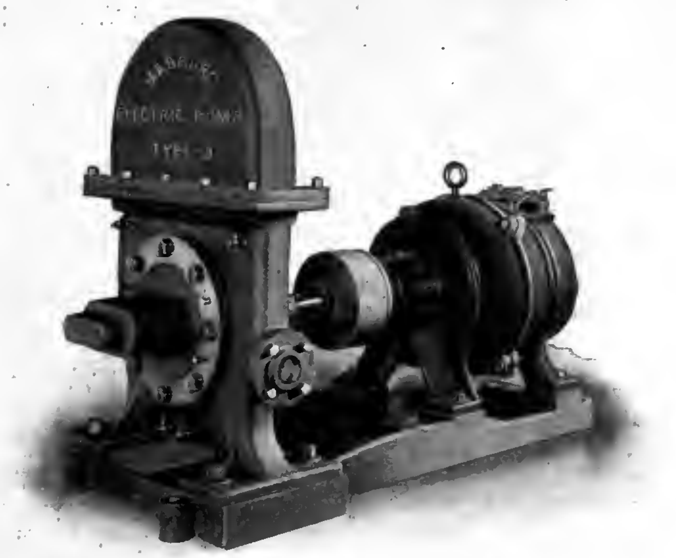
England, is briefly described in "Engineering," on the authority of figures given by Mr. F. R. O'Shaughnessy. The sewage contains acid wastes and the spent liquors of breweries, paper mills and fellmonger works as well as the household sewage of a population of 815,000. This is discharged into three tanks having a total capacity of 440,000 cubic feet. Each tank is divided into three basins, where much of the suspended matter settles. From the tanks the partly clarified sewage passes into sixteen small tanks having a total capacity of 728,960 cubic feet, which act as septic tanks. After remaining eight hours in them, the septic sewage is discharged over the land of the large farm on which the works are situated. The sludge is mostly buried, and the introduction of the septic system has reduced the total quantity to be handled to less than half of the amount which resulted from the chemical treatment formerly in use.

Two Pumping Devices.

The E. W. Bliss Company, Brooklyn, N. Y., is making two pumping devices for buildings and country estates which possess several interesting features. The first is the Marburg electric pump, consisting of a rotary pump with two interlocking wheels like those used in pressure blowers, driven by a direct-connected motor mounted on the same baseplate. This type of pump has a continuous discharge and steady motion which eliminates pounding, and the apparatus designed by Mr. Marburg has special advantages due to the arrangement of the suction and delivery openings in such a manner that the internal pressures of the water have been balanced and the friction thus reduced to a minimum. These pumps are made with capacities ranging from 300 to 3,500 gallons per hour and designed to work against heads between 30 and 175 feet.

The second device is the Bliss-Heath pumping engine, which is of the atmospheric type. It consists of a low-pressure tubular boiler, an atmospheric engine driving a water pump, and a single-acting air pump. The entire apparatus is designed to be perfectly safe in the hands of the most thoughtless laborer. The boiler works under a pressure about equal to that of a domestic tea kettle, and the safety valve is a light lid or cover fitting a large opening in the top of the boiler. The engine operates by expelling air from the power cylinder by admitting steam, which is exhausted in turn into the condenser, in which a constant vacuum is maintained. Steam is then admitted into the power cylinder, breaking the vacuum and giving the piston the required impulse. During the winter the apparatus can be worked by steam from any ordinary low-pressure heating boiler, thus making a separate fire in the engine boiler unnecessary. The apparatus is sold in four sizes, with capacities of 600, 1,200, 2,000 and 3,000 gallons per hour.

THE BLISS-HEATH PUMP.



THE MARBURG ELECTRIC PUMP.

Trade Publications.

A beautifully printed album of engravings has been issued by the Crocker-Wheeler Co., Ampere, N. J., to illustrate some of the applications of the electric motor to driving machinery of many types.

Eighteen months ago a new paint called "Protectus" was placed on the market by The Protectus Co., North American Building, Philadelphia. Its advantages are stated to lie in the vehicle, the base of which is a mineral oil, instead of in the pigment. The company has just issued a pamphlet describing a number of tests of the paint and explaining its uses on metal and steel for various classes of service.

The Caskey punch, described in a pamphlet from F. F. Slocomb & Co., Wilmington, Del., consists of a movable frame having a punch operated by pressure oil. The oil is forced to the punch by the piston of a cylinder in which the motion of the parts is produced by compressed air. The apparatus has been tested in a number of large works and is now placed on the market in sizes with reaches of 3¼ to 12 inches.

The General Electric Co., Schenectady, has added three new numbers to its excellent series of bulletins, No. 4,285 on the four forms of automatic circuit breakers for 500-volt direct-current circuits, No. 4,286 on an adjustable shunt field coil for Thomson recording wattmeters to counteract the friction of the meters, and No. 4,288 on slow and moderate speed belt-driven generators. Flyers have also been issued on the renewal parts for electric brakes, blue-printing with enclosed arc lamps, porcelain knobs and cleats and fuse wire, and a general description of transformers for high potential is given in a special manual.

The Electric Storage Battery Co., Allegheny Ave. and 19th St., Philadelphia, has issued a number of circulars which will appeal particularly to the designers of small electric lighting plants for country estates and situations requiring similar service. Many illustrations are given of such plants, and there are also notes on line batteries for voltage regulation and use of storage batteries in commercial electric automobile service.

The Pierce, Butler & Pierce Mfg. Co., Syracuse, N. Y., is distributing a handsomely illustrated pamphlet explaining in detail the construction of the Florida and Tropic boilers for steam and hot water respectively.

The construction of the Chicago cube concrete mixer is described in a catalogue issued by the Municipal Engineering & Contracting Co., Manhattan Bldg., Chicago. It is made in sizes from ½ to 2 cubic yards and in portable, semi-portable and stationary types, and one of its features is a measuring hopper in which the materials for a batch are placed in proper proportions while the mixer is preparing the preceding batch.

A catalogue of air compressors driven by special electric motors, mounted so as to form compact units, has been issued by the Christensen Engineering Co., Milwaukee, and 153 Broadway, New York. These compressors range in capacity from 4 to 1,000 cubic feet per minute, and are built in several types for different classes of service. One portion of the pamphlet illustrates a number of portable plants for use with pneumatic tools where an expensive piping system is undesirable.

A large number of designs of lawn fencing made of wire are illustrated in a 48-page catalogue from the Up-to-Date Mfg. Co., Terre Haute, Ind. These can be used with wooden posts if desired, but ornamental steel and cast-iron posts are made specially for the purpose, and gates, both single and double, are provided with the different styles.

The American Conduit Mfg. Co., New Kensington, Pa., has issued a folder describing the iron armored conduit tubing it is making for electric wiring.

The Philadelphia Machine Tool Co., 443 North Darien St., Philadelphia, has issued a folder describing its machines for testing chains, rope, long bars and the like. Large chain is proved in 15-fathom lengths which makes a special apparatus like this necessary.

The United Telpherage Co., 20 Broad St., New York, has issued several circulars illustrating the application of its system of overhead tracks and motors for handling baggage at railway stations, stone buckets in cement works and large packages in a paper-bag mill.

Personal and Obituary Notes.

Mr. Henry F. Hornbostel has been appointed consulting architect for the Department of Bridges, New York City.

Mr. William Kleefeld, Jr., has been appointed supervisor of bridges on the Middle Division of the New York Central & Hudson River Railroad, with headquarters at Utica.

Col. H. G. Prout, editor of the "Railroad Gazette," has received an honorary degree as Master of Arts from Yale University. He is a graduate of the University of Michigan in civil engineering.

The Pennsylvania Steel Company has located its Northwestern office in the Western Union Building, Chicago, in charge of Mr. Clifford J. Ellis, sales agent, and Mr. Robert E. Belknap, assistant sales agent.

Mr. C. A. Wentworth, of Somerville, Mass., and Mr. George A. McKay, of Troy, N. Y., have scored the highest marks in a competitive examination which will entitle them to appointment as civil engineers in the U. S. Navy.

Mr. C. E. Cartlidge has been appointed chief bridge engineer of the Chicago, Burlington & Quincy Railway, with headquarters at Chicago. Mr. George H. Bremmer has been appointed engineer of the Illinois lines, with jurisdiction in the States of Illinois, Wisconsin and Minnesota, and Mr. Frank Beckwith, engineer of the Iowa lines, with headquarters at Burlington.

Capt. M. G. Howe, M. Am. Soc. C. E., died June 19, at his home in Houston, Tex., after many months of poor health. He was born at Methuen, Mass., in 1834, and was a graduate of Dartmouth College. He had been a resident of Houston since 1859, when he entered upon an almost continuous railroad career, chiefly with the Houston & Texas Central Railroad, of which he became chief engineer. He served in the Confederate Army, rising to the rank of captain in the engineering corps.

Ira Alexander Shaler died on June 29 at the Presbyterian Hospital, New York, from the results of an accident received on June 17 in the Park Avenue tunnel of the New York Rapid Transit Railway. He was not quite 40 years old, yet in his brief career he had achieved the distinction that usually comes only later in life. After graduating from Cornell in 1884, he entered the employ of the Croton Aqueduct Commission, rising from a rodman's position to that of assistant engineer. He recognized very early, however, that contracting was his most congenial field, and in 1889-90 built several small water-works plants. In 1890 he became one of the firm of Washburn, Shaler & Washburn, and built the Titicus dam for the New York water-works. In 1894 he was the engineering member of J. W. Hoffman & Co., and built one of the Philadelphia electric roads. Later he served again as assistant engineer of the Croton Aqueduct Commission, but it was not long before he engaged once more in contracting. Some of his interesting plant for building the Gull Island fortifications was described in The Engineering Record of December 2, 1899. He was the engineer for John D. Crimmins while the latter was constructing many of the electric railways in New York. During all these years he had been gaining an unsurpassed reputation for care, skill and energy in the management of work, and it was accordingly expected when he undertook the construction of the tunnel where his fatal accident occurred, that this difficult enterprise would be carried through to a successful conclusion in a similarly notable manner. But, on the contrary, the contractor met with one misfortune after another, all borne with a courage that made even the people suing him for damages admire the steadiness with which he carried his great responsibilities.

The Feed-Water Heater in the Chicago Tribune Building, mentioned on page 608 of The Engineering Record of June 28, is a closed Bundy heater made by the A. A. Griffing Iron Company, and not an open heater, as stated erroneously.

Electric Power Transmission is to be tried in the refractory brick works of the Fayette Manufacturing Company, Chester, Pa. Induction motors will be used to drive the plant for mixing and grinding the materials, conveying them about the works and pressing them. A three-phase Westinghouse equipment has been purchased for the purpose.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Montreal, Que.—Bids are wanted July 8 for furnishing and delivering for the year 1902 special castings, brass castings, etc. L. O. David, City Clk.

Newcastle, N. B.—Bids are wanted July 15 for constructing a covered concrete and masonry reservoir. Address R. T. D. Aitken, Town Clk.; Willis Chipman, Ch. Engr., 103 Bay St., Toronto, Ont.

Brockport, N. Y.—The Village Trustees are reported to have appointed a committee to consider the question of establishing a municipal water works plant.

Canajoharie, N. Y.—The Palatine Bridge Water Co., of Canajoharie, has been incorporated with the Secretary of State. Its capital stock is placed at $10,000, and the directors for the first year are David Gring, of Newport, Pa.; J. D. Lanes, of Mechanicsburg; M. E. Johnson, of Canajoharie, and E. H. Ireland, of Palatine Bridge.

Biloxi, Miss.—This city has sold water works bonds to the amount of $40,000.

Baraboo, Wis.—The Water Wks. Com. is reported to have engaged an engineer to prepare plans and specifications for the new water works plant.

Indianapolis, Ind.—The Bd. of Pub. Wks. has approved in part the water main extensions (in all 8 miles are provided for) to be made by the Indianapolis Water Co. for the recently annexed territory of Irvington and Tuxedo.

Wallingford, Conn.—The Water Comrs. have voted to take land necessary for a storage reservoir for its water supply on Muddy River, including land for flowage, dam, etc.; dam to be built according to plans prepared by Engr. McKenzie.

Grafton, W. Va.—The Valley Falls Power Co., of Grafton, has been incorporated to operate water and electric light plants; capital stock, $50,000. Incorporators: John T. McGraw, George W. Whitescarver, of Grafton; James Conning, of Valley Falls, W. Va., and others.

Eldon, Ia.—Town Clk. Ed. J. Moore writes that it is proposed to change the location of the water works plant to river instead of wells. F. G. Isbell, Engr. in Charge.

Trenton, N. J.—The estimated cost of extending the water mains to Hillcrest is about $12,000.

Peabody, Mass.—Bonds to the amount of $150,000 are stated to have been voted for water works and $95,000 for a new school.

Gueydan, La.—The Gueydan Water Works & Power Co. has been organized, with a capital of $10,000. Bd. of Directors: W. L. Doss, H. L. Gueydan, J. G. Neells, and others.

Providence, R. I.—Bids are wanted July 15 for labor and material necessary for constructing a slow-sand filtration plant for the city, as advertised in The Engineering Record.

Ft. Revere, Mass.—Capt. Alfred M. Palmer, Q. M., U. S. A., Boston, writes that the following bids were opened June 19 for furnishing labor and material and constructing a water tower and standpipe at this Post: C. N. Taylor, Wellesley, Mass., rock, $15,900 and $15,700; brick, $14,400; granite, $16,500. R. Baffrey, 1123 Bway., New York, $11,980 (awarded). Walsh's Holyoke Steam Boiler Wks., Holyoke, Mass., steel standpipe, $2,960.

Troy, N. Y.—City Engr. E. R. Cary writes that the contract for the completion of Quakenkill dam was awarded to E. H. McKenna on June 28, for $4,562. The other bidders were P. Harrison Sons Co., at $5,874, and Behan & Cavanaugh at $6,843.

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until July 18 for furnishing material and erecting, testing and painting steam and feed water piping with fittings, separators, filters, galleries and platforms in H. S. Station No. 1. Hiram Phillips, Pres.

Chicago, Ill.—Contract Clk. Frank Murphy writes that the time for receiving bids for furnishing materials and constructing in the Chicago Ave. pumping station one electric traveling crane, with maximum lifting capacity of 20 tons, has been postponed until July 11. F. W. Blocki, Comr. of Pub. Wks.

Wheaton, Ill.—See "Schools."

Geneseo, Ill.—City Clk. Henry F. Hoeft writes that the contract for furnishing and delivering 9,600 ft. of 4-in. cast-iron pipe, 5,280 ft. of 2-in. wrought-iron, lap-welded steam pipe, 19 Matthews hydrants and 6 4-in. valves has been awarded to Doremus & Becker, of Geneseo, for $4,810.

Bloomington, Ill.—Ordinances have been passed for water mains on 3 streets. Elmer Folsom, City Engr.

Houston, Tex.—T. W. House writes that the Clark Rice & Irrigation Co., of which he is one of the incorporators, proposes to construct an irrigation system. Ross L. Clark, of Port Lavaca, Tex., Treas.

Bird Island, Minn.—Recorder Frank Murray writes that at a recent election it was voted to construct a system of water works at a cost of $8,000.

Henry, Ill.—Mayor A. G. Humphrey writes that it is proposed to construct water works at a probable cost of $40,000.

Whatcom, Wash.—City Clk. Wm. H. Hildebrand writes that on June 21 it was voted to issue bonds to the amount of $30,000 for the purchase of cast-iron water pipe.

Piqua, O.—W. B. Mitchell, Secy. Bd. of Water Wks. Trus., writes that on June 24 there were 34 bids received for furnishing pumps and boilers, as advertsed in The Engineering Record. Contracts for same were awarded as follows: To John H. McGowan & Co., of Cincinnati, for one 14 and 25x16x24-in. duplex pump, for $2,900. To Atlas Engine Co., Indianapolis, Ind., 2 horizontal tubular boilers, 66-in.x16 ft., for $1,390.

Philadelphia, Pa.—The only bid received June 25 by Wm. C. Haddock, Dir., Dept. of Pub. Wks., for erecting an administration building and pumping station at Upper Roxborough filters, and for constructing a system of baffles for the Lower Roxborough reservoir, was from Daniel J. McNichol, Betz Bldg., at $37,800 for the building and $13,390 for the baffles.

Sugar City, Colo.—Town Clk. and Recorder Sherman Farr writes that on June 13 a vote was taken in favor of constructing water works.

Austin, Pa.—Bids are wanted July 10 for furnishing materials and constructing a water works system, as advertised in The Engineering Record.

Mobile, Ala.—The Council has authorized Com. No. 6 to look into the possibility of purchasing the Bienville water works.

Los Angeles, Cal.—The Suburban Water Co. is stated to have been incorporated, with a capital of $30,000. Principal place of business, Los Angeles. Directors: Valentine Peyton, Arthur L. Hawes, John D. Pope, of Los Angeles, and others.

Blairsville, Pa.—The issue of $7,000 water extension bonds is said to be under consideration. M. E. Brown, Burgess.

Nassau, N. Y.—Bonds to the amount of $13,500 were voted at the recent election for a public water supply to be taken from Lyon's Lake.

Albany, Minn.—This village has sold water works bonds to the amount of $7,000.

Westerville, O.—Press reports state that the Water Wks. Trustees have finished drilling 3 wells which will have a capacity of 500,000 gal. daily, and that plans and specifications will soon be completed and contracts let for the construction of the water works system.

Comanche, Tex.—Local press reports state that Engr. Haley estimates the cost of a system of water works at $17,000.

Cullom, Ill.—This village is reported to have voted to establish a system of water works.

Enfield, N. H.—Bonds to the amount of $45,000 have been voted for a system of water works. E. B. Huse, Chmn. of Water Com.

Findlay, O.—Press reports state that the project to pipe water for this city from Mineral Springs, a distance of 10 miles, has been approved by the State Bd. of Health.

Philadelphia, Pa.—Local press reports state that the contract for furnishing gas engines for the high pressure fire pumping station to be erected at Delaware Ave. and Race St. has been awarded to M. R. Muckle & Co., of Philadelphia. They offered to furnish four vertical triplex double-acting piston or plunger pumps, connected with three cylinder driving engines, and two smaller pumps of the same type for $116,242. Their bid for extra pumps of the large type was $20,957 and for the smaller ones $9,378 each.

Milford, Ind.—The Town Bd. has granted a franchise to the Milford Water Co.

Duquoin, Ill.—Press reports state that the Ill. Central R. R. Co. proposes to construct a 60,000,000-gal. reservoir at Duquoin, on the St. Louis division. W. J. Harahan, Ch. Engr., Chicago, Ill.

Washington, D. C.—Congress has appropriated $600,000 for the filtration plant.

Horseheads, N. Y.—The proposition to secure a gravity system of soft water is under consideration.

Grinnell, Ia.—It is stated that a soft water supply is to be installed at an estimated cost of $15,000.

Langford, S. D.—The Langford Artesian Water Co. has been incorporated, with a capital of $5,000. Incorporators: Richard Williams, P. H. Gilbert, Q. A. Krieger, and others.

McRae, Ga.—At a recent election it was voted to issue bonds for water works and electric lights.

Tacoma, Wash.—Mayor Louis D. Campbell, in a communication to the City Council, recommended that steps be taken at once to procure an adequate supply of good water for the city. The Green River is said to be the only sufficient and permanent all-gravity water supply available. Estimated cost of securing a supply from this source is given as $500,000.

Portsmouth, Va.—Local press reports state that the Portsmouth, Berkley & Suffolk Water Co. proposes to put in a pumping system that will supply water direct from Lake Kilby to the main pipes. Geo Hornung, Gen. Mgr.

Sutherland, Ia.—Bonds to the amount of $4,500 have been voted to start work on the construction of a system of water works.

Berlin, Pa.—The Berlin Water Co. has been given the exclusive right to lay mains, etc., in the Boro. of Berlin. O. P. Shupe and W. H. Kalp, of Mt. Pleasant, are Pres. and Secy., respectively, of the Co.

Russell, Ia.—At a recent election a vote was taken in favor of installing water works. Estimated cost, $5,000.

Waco, Tex.—The City Council has voted to issue bonds to the amount of $200,000 for water works and an electric light plant, and the Mayor and Finance Com. has been authorized to do such preliminary work as may be necessary to secure right of way, etc.

Hamilton, O.—Dabney H. Maury, of Peoria, Ill., in a recent report to the Bd. of Control on the city's water works plant, recommends the installation of a new 6,000,000-gal. pumping engine, with necessary boilers, and extension of buildings; also supply reservoir wells, supplementary pump, motor and new pipe line, new wet well, connection of old supply to new pipe line, and supplementary pump house. Total estimated cost, $110,000.

Lancaster, Pa.—The Special Water Com. of Councils has recommended that the proposition of the Lancaster Water Co. to lease the water plant of the city for $900,000 be refused.

Terrell, Tex.—Water works bonds to the amount of $6,000 were voted at the recent election.

Ennis, Tex.—A committee has been appointed to consider plans for improving the water works.

Black River, N. Y.—B. N. Scott and H. C. Dexter are members of the committee of citizens which is making investigations with a view to installing water works.

Oxford, Ind.—The Oxford Water Co. has filed articles of incorporation, with a capital of $25,000. Directors: Sam. V. Perrott, Henry C. Ulen, Jr., and Albert G. Perrott.

Fairhaven, Wash.—Bonds to the amount of $60,000 are stated to have been voted for water works improvements.

Sacramento, Cal.—The City Bd. of Trustees has under consideration 2 propositions for a water supply for the city. One proposition offered by A. M. Hunt for the Eldorado & Deep Gravel Ditch Co. and the Diamond Ridge Ditch Co. proposes to bring water of the Eldorado ditch system to a point near Folsom and thence pipe it to Sacramento. The other proposition was offered by R. G. Hanford, representing New York capitalists, and contemplates carrying the water of North Fork ditch from the $100,000 stone dam near Auburn, in a cemented and covered ditch 25 miles to the settling and storage reservoirs above Orangevale, filtering the water there and piping thence in 30-in. steel mains to Sacramento, 22 miles. Mr. Hanford asks for a 20-year contract from the city, with the privilege of extension on its part for 10 years more, the city to pay a minimum of $80,000 per year for the water; daily supply, 6,500,000 gal.

SEWERAGE AND SEWAGE DISPOSAL.

Dayton, Ky.—The City Engr. estimates the total cost of constructing a sewerage system at about $100,000.

Indianapolis, Ind.—The Bd. of Pub. Wks. has approved plans of the City Engr. for the Northwestern Ave. sewer; length of sewer, 7,300 ft.; at its outlet it will be 5 ft. high and 10 ft. wide, and it will diminish gradually until it reaches an oval, 2x3 ft., and then end in pipe sewer from 24 to 10 in. in diameter; there will be 51 catch basins, 22 manholes and 35 inlets. Probable cost about $60,000.

Roselle, N. J.—At a recent special election Roselle Park voted in favor of sewer construction.

Washington, D. C.—Among the appropriations made by Congress are the following for work on the sewerage system in the Dist. of Columbia: Continuing construction of sewage disposal system, pumping station and for machinery with which to equip it, $250,000; cleaning and repairing sewers, $58,000; main and pipe sewers and receiving basins, $50,000; suburban sewers, $50,000; continuing boundary sewer to 22d and A Sts., N. E., $40,000; completing east side intercepting sewer, $52,000; continuing low area trunk sewer, $60,000; B St. and New Jersey Ave. sewer, $50,000; trunk sewer for western part of Georgetown, $20,000, and authority to complete said sewer at a cost not to exceed $42,000; additional work to cost $25,000.

Delray, Mich.—Bonds to the amount of $65,500 have been authorized for a sewer system.

Akron, O.—The City Council has adopted a resolution to construct a main trunk sewer in Dist. 9.

Canton, S. D.—Bids are wanted July 14 for constructing a sewer system. W. S. Ingham, City Aud.

Rock Rapids, Ia.—This town is reported to have contracted with C. F. Loweth, of St. Paul, Minn., to prepare plans and specifications for a system of sewers.

Antigo, Wis.—The Council has voted to construct a system of sewerage, according to local press reports.

Newark, N. J.—The lowest bid received June 26 for building Section 4, Second and Third Divisions of the West Branch of the Joint Outlet Sewer, was from Earle & Dougherty, of Jersey City, at $51,754.

Buffalo, N. Y.—Bids are wanted July 16 for constructing a 24-in. brick and a 15-in. tile sewer in a portion of Hayes Pl. and a 10-in. tile sewer in Zittle St. Francis G. Ward, Comr. of Pub. Wks.

Cleveland, O.—Bids are wanted July 8 for constructing sewers in portions of several streets. Chas. P. Salen, Dir. Pub. Wks.

South Brooklyn, O.—Bids will be received by W. T. Pupikofer, Village Clk., until July 19 for constructing sewers in portions of numerous streets.

Newark, N. J.—See "Bridges."

Des Moines, Ia.—Bids will be received by the Bd. of Pub. Wks. until July 21 for constructing 470 lin. ft. of 24-in., 1,130 lin. ft. of 18-in., and 7,115 lin. ft. of 12-in. vitrified clay pipe sewers. Bids will be received by the Bd. of Pub. Wks. until July 22 for constructing brick and pipe sewers as follows: 40 lin. ft. of 48-in., 4,320 lin. ft. of 42-in. and 790 lin. ft. of 36-in. 2-ring brick sewers; also 2,360 lin. ft. of 18-in. and 1,820 lin. ft. of 15-in. clay pipe sewers. Bids will also be received until July 22 for constructing the Highland Park lateral sewers, requiring about 27,330 lin. ft. of 12-in. vitrified clay pipe. J. E. Stout, Chmn.

Geneva, O.—City Clk. A. H. Reed writes that on June 26 it was voted to issue $25,000 bonds for sewerage.

San Juan, P. R.—Bids are wanted July 18 for furnishing and delivering upon the wharf at San Juan a quantity of salt-glazed sewer pipe, branches and Y pieces, as advertised in The Engineering Record.

Bloomington, Ill.—Ordinances have been passed for pipe sewers on 3 streets. Elmer Folsom, City Engr.

Fresno, Cal.—A storm water sewer system is to be constructed for the business portion of the city, at a cost of about $35,000. Sewers to be of brick, and laterals of pipe, 18,000 ft. in all, 30-in. to 12-in. in diameter.

Beloit, Wis.—The Bd. of Pub. Wks. will receive bids July 7 for 2,700 ft. of 20-in. and 900 ft. of 8-in. pipe sewers. Robt. Caldwell, City Engr.

Columbus, Miss.—An additional 10 miles of sewers will be built, work to be done by the city. J. L. Ludlow, of Winston, N. C., Engr.

East Grand Forks, Minn.—Bids for furnishing and laying 1,750 ft. of 12-in. and 490 ft. of 8-in. sewer pipe, 18 catchbasins and 6 manholes, will be opened by the City Council on July 15. Henry Harn, Recorder.

Rochester, N. Y.—The Common Council on June 24 passed final ordinances for sewers in Colvin and Barton Sts.

Albany, N. Y.—Bids will be received by the Bd. of Contract & Supply until July 7 for constructing the Central Ave. sewer, consisting of 1,330 lin. ft. of 10 and 12-in. pipe, and 1,130 lin. ft. of 15-in. double strength pipe. Bids are also wanted for constructing pipe sewers in portions of 4 streets. Isidore Waschman, Clk.

Binghamton, N. Y.—Bids are wanted July 22 for constructing sewers in portions of 4 streets. I. C. Hull, City Clk.

Worcester, Mass.—The Com. on Sewers of the Council voted to recommend the adoption of an order for the construction of a sewer and pumping station in Worcester Highlands, at an estimated cost of $7,500.

Griffin, Ga.—Local press reports state that the City Council has decided to construct a sewer system.

Plain City, O.—The City Council is said to be considering plans for a drainage system.

Indiana, Pa.—The Council has passed an ordinance providing for the construction and maintenance of filter bed or disposal plant and mains for public sewerage for the Boro. of Indiana and the extension of necessary sewer mains beyond limits of borough to the disposal plant.

E. St. Louis, Ill.—Bids are wanted July 8 for constructing 18,000 lin. ft. of 6 to 24-in. sewers, 35,000 cu. yds. of sewer excavation and refilling. L. L. Harper, Chmn. Bd. Local Improv.

Lafayette, Ind.—Bids will be received by the Co. Comrs. until July 11 for 15 steel pipe culverts and 5 concrete or vitrified brick arch culverts. G. H. Stevenson, City Engr.

La Grange, Ga.—At the election held June 23 bonds to the amount of $25,000 were voted for the construction of a system of sewerage.

Napakoneta, O.—Riggs & Sherman, of Toledo, are stated to have received the contract for the preparation of plans for a sewerage system.

Galveston, Tex.—See "Paving and Roadmaking."

Pueblo, Colo.—Local press reports state that the following bids were opened June 23 for the construction of a combined storm and sanitary sewer system for this city: J. M. O'Rourke Const. Co., Denver, $335,889; The Colorado Co., Denver, $298,254.

Seattle, Wash.—An ordinance before the City Council calls for an expenditure of $20,000 for the building of septic tanks on the shores of the lakes to consume the sewage of the city.

Worcester, Mass.—The City Council recently made a partial inspection of the city sewer system, one of the objects of the trip being to consider the need of at least 50 new filtration beds at the sewage purification works at Quinsigamond. The city has already acquired the land for these beds and the estimated cost of construction has been placed at $100,000. It is not proposed to build all of these beds at one time.

Cincinnati, O.—The Bd. of Pub. Service has approved specifications for a sewer in Observatory Ave. Estimated cost, $7,028.

Maryville, O.—The business men are stated to have petitioned the City Council for a public sewer system.

Salem, Mass.—The Com. on Sewerage of the City Council has voted to employ Guy W. Ricker, of Salem, to make plans for the South Salem intercepting sewer.

BRIDGES.

Newport, Va.—Press reports state that the Hampton Roads Ry. & Electric Co. has asked the city for permission to construct a bridge at 26th St.

St. Paul, Minn.—Local press reports state that the State Bd. of Control has awarded the contract for constructing a 387-ft. steel truss bridge across Vermilion River, near Hastings Asylum, to the American Bridge Co. at $5,000. The main span is to be 95 ft. long.

Sioux Falls, S. D.—The City Council has adopted a resolution to compel the Great Northern, the Omaha and the Chicago, Milwaukee & St. Paul R. R. Cos. to construct a viaduct at 8th St.

South Bend, Ind.—Fred. Hoffman, Crawfordsville, Ind., has received, according to local press reports, the contract to construct a bridge across the race at Colfax Ave. for $8,495.

Benicia, Cal.—It is stated that the officials of the Southern Pacific R. R. Co. are considering the construction of a bridge across the Straits of Carquinez, from Benicia to Port Costa. W. Hood, Ch. Engr., San Francisco.

Flint, Mich.—Local press reports state that the construction of a bridge at Saginaw St., at a probable cost of $21,458, is contemplated.

Newark, N. J.—According to local press reports plans are about to be adopted for a through girder steel and iron bridge which the Delaware, Lackawanna & Western R. R. Co. intends constructing across Broad St., this city.

Pittsfield, Mass.—Collins & Norton have submitted plans and specifications for an iron bridge to be built at Dalton Ave.

Charleston, S. C.—The Senate has passed bills authorizing the construction of 2 bridges across Ashley River, in the counties of Charleston and Dorchester, S. C.

Pierre, S. D.—A bill has passed both the House and Senate authorizing the Duluth, Pierre & Black Hills R. R. Co. to construct a bridge across Missouri River at Pierre.

Solebury, Pa.—The Co. Comrs. have approved plans for an arch bridge to be built by the Supervisors of Solebury Township.

Middlebourne, W. Va.—D. Hickman, Clk. of the Tyler Co. Court, writes that the Riverside Bridge & Machine Wks., of Wheeling, have secured the contract for the iron superstructure for the Shiloh bridge, at $3,734, and the contract for the stone work has been awarded to B. F. Pipes, of Shiloh, for $5,175.

Three Rivers, Mass.—At a Town Meeting held recently, $6,000 was appropriated for the construction of a bridge, with concrete floor, across Quaboag River at Three Rivers.

Altoona, Pa.—City Engr. Harry Linton writes that plans are being prepared for a highway bridge near the sewage filter beds.

Akron, O.—Bids are wanted July 26 for the construction of a concrete-steel arch bridge at Falor St., width over all 43 ft., 5 arches, span 40 ft. 3 in. Estimated cost, $25,000. Plans and specifications on file at the office of City Engr. J. W. Payne and at office of Osborn Engineering Co., Cleveland, O.

Port Royal, Tenn.—It is stated that the construction of a bridge across Red River is being agitated.

Tuscaloosa, Ala.—B. H. Hardaway is reported to have received the contract to repair the Foster's Ferry bridge at $6,150.

Macleod, N. W. Ter.—Press reports state that the replacing of the bridge washed away by the freshets is being agitated.

Artemus, Ky.—It is stated that the Co. Comrs. will soon receive bids at Knox for the construction of a $15,000 bridge 375 ft. long across Cumberland River at Artemus.

Lethbridge, N. W. Ter.—According to reports the bridge which was destroyed by the floods last month may be replaced in the near future.

Grafton, Pa.—J. J. Neel, the Comr. appointed by the Co. Court to report on the condition of the bridge at Grafton, reports in favor of removing present structure and constructing a steel bridge at an estimated cost, including the removal of present structure, of $11,560.

Ft. Plain, N. Y.—Bids will be received at Albany by Chas. S. Boyd, State Supt. of Pub. Wks., until July 10 for constructing a bridge across Otaquago Creek, in Ft. Plain.

Craig, Mont.—Bids will be received by the Comrs. of Clarke & Lewis Co. until July 19 for constructing a steel or combination bridge across Missouri River at Craig. Plans and strain sheets are to be furnished with bids. Sidney Miller, Co. Clk., Helena.

St. Clairsville, O.—Bids will be received by the Bd. of Co. Comrs. until July 24 for furnishing material and constructing the stone substructure of a bridge on McMahons Creek Pike, in Pultney Township. M. Aldredge, Co. Aud.

Noblesville, Ind.—Bids will be received by the Bd. of Co. Comrs. until July 8 for furnishing and constructing a steel bridge, 50-ft. span, and a steel bridge, 65-ft. span, across Stony Creek near Dublin; also a steel bridge, 52-ft. span, across Mud Creek near Fishers Station. J. A. Mitchell, Engr.

North Loup, Neb.—It is stated that bids will be received by the Co. Comrs. at Ord until July 15 for constructing a 320-ft. bridge across North Loup River, about 2 miles northeast of North Loup. Address Co. Clk.

Erie, Kan.—Bids will be received by the Co. Comrs. until July 12 for constructing 3 steel bridges, to be located as follows: 1 across Village Creek, the main span to be 65 ft. long, the northern approach 40 ft. and the southern approach 65 ft. long; 1 across Neosho River, the main span to be 125 ft. long, the northern approach 28 ft. and the southern approach 36 ft. long; and 1 across Neosho River, the main span to be 150 ft. long, the east approach 75 ft. long and the west approach 30 ft. long. B. W. Garvin, Co. Clk.

Newark, N. J.—Bids will be received by the Bridge Com. of the Co. Bd. of Chosen Freeholders until July 7 for constructing the following bridges: Stone abutments and steel beam bridges on Turrell Ave. and Meadow Brook Lane, South Orange; culvert on Avondale Road, Nutley; extension of steel superstructure and brick bridge on Glenwood Ave., Bloomfield; stone abutments and steel beam bridge on Cross St., Montclair; also for 2,000 ft. of 24-in. stoneware pipe. Jas. Owen, Co. Engr.

Allentown, Pa.—It is stated that the building of a bridge from the 10th to the 6th Ward is being agitated.

Cincinnati, O.—The Miami & Erie Transportation Co. has asked the Co. Comrs. for permission to strengthen and lengthen the following bridges: Ross Ave., Cook Ave., 2d St., Carthage, Paddock Road and Edgemont Ave. structures.

Washington, D. C.—A bill has passed both the House and Senate authorizing the W. Elizabeth & Dravosburg Bridge Co. to construct a bridge across Monongahela River, in Pennsylvania.

Richmond, Va.—See "Electric Railways."

Houston, Tex.—City Engr. Dormant has prepared plans and specifications for constructing a viaduct across Montgomery Ave. crossing as a solution of the question of allowing the Southern Pacific R. R. to build 4 more tracks on the avenue.

Hammond, Ind.—The House and Senate have passed a bill authorizing the N. Y., Chicago & St. Louis and the Chicago & St. Louis R. Rs. to construct a bridge across Calumet River at Hammond.

Morgantown, W. Va.—The South Morgantown Bridge & Improvement Co. has been incorporated, with a capital of $50,000, for the purpose of improving the southern part of Morgantown by building bridges and paving and constructing roads.

Medford, Ore.—C. D. Redinger is reported to have secured the contract to construct a 2-span steel bridge, each span 110 ft. long, across Bear Creek at 7th St., for $5,995.

Akron, O.—The Northern Ohio Traction Co. has, according to reports, awarded the contract to construct a concrete and steel viaduct across Cuyahoga River at the gorge, 2 miles above this city, to the American King Bridge Co., of Cleveland, for $50,000.

Paterson, N. J.—Bids will be received at Paterson until July 8 by the West Milford & Wayne Bridge Committees of the Bd. of Co. Chosen Freeholders, David Wickham and Garret Berdan, Chmn., respectively, for constructing the following bridges: Steel beam and concrete arch bridge with macadam roadway on the Paterson and Hamburg Turnpike above Smith Mills, West Milford Township, and a steel beam and brick arch bridge with macadam roadway in Wayne Township. Wm. L. Whitmore, Co. Engr., Rm. 29, Savings Institute Bldg., Paterson.

Kansas City, Kan.—A bill has passed the Senate authorizing the construction of a bridge across Missouri River, about 5 miles north of the Kaw River in Wyandotte Co., Kan., and Clay Co., Mo., and to make the same a post route.

Paducah, Ky.—See "Electric Railways."

Brooklyn, Minn.—Bids are wanted July 7 for rebuilding bridge No. 160, Brooklyn. Geo. W. Cooley, Co. Surv., Minneapolis.

Braceville, O.—Bids are wanted July 11 for constructing an iron bridge across Mahoning River at Braceville. Chas. R. Shelby, Co. Aud., Warren.

Tremont, Pa.—Bids are wanted July 8 for constructing 2 iron bridges. J. H. Faust, Secy., Tremont.

Walhalla, S. C.—Bids are wanted July 10 for constructing a steel bridge. F. A. H. Schroder, Co. Clk.

Glen Cove, L. I., N. Y.—Local press reports state that the construction of a $20,000 iron bridge across the lower lake, connecting North and South Glen Cove, is being agitated.

Pekin, Ill.—The Highway Comrs. of Pekin Township have petitioned the County for assistance in the construction of an iron bridge across Lick Creek, estimated to cost $3,000.

PAVING AND ROADMAKING.

Upper Sandusky, O.—The County Comrs. on June 28 sold $32,700 road improvement bonds.

Mobile, Ala.—The City Council on June 27 adopted the 2d Dist. paving scheme, which provides for the paving with asphalt, on concrete foundation, of numerous streets, the paving with brick on concrete foundation of 1 street and the paving with brick on sand foundation of several streets; curbing for this improvement to be of both stone and of concrete.

Michigan City, Ind.—H. M. Miles, City Engr., writes that bids will be received until July 21 for improving 8th St. by paving with asphalt, 5,500 sq. yds.

Pasadena, Cal.—It is stated that bids will be received by the City Clk. until July 14 for furnishing an improved road roller, to be delivered Dec. 1.

Massillon, O.—The City Council has adopted a resolution providing for the paving with brick blocks of Plum, Tremont, Oak and other streets; total estimated cost, $13,023, and Mill St., total estimated cost, $24,146.

Perth, Ont.—The Lanark County Council has decided to issue $85,000 bonds, for the purpose of constructing a system of good roads throughout the county.

Milwaukee, Wis.—Local press reports state that the Reliance Contracting Co. secured the work of paving a portion of 13th St., an area of 4,911 yds., with brick at $2.16 a yd., and Alfred Johnson secured a contract for paving 24,710 sq. yds. on 3d St. with brick at $2.23 a yd.

New Brighton, S. I., N. Y.—Bids will be received by Geo. Cromwell, Boro. Pres., 1st Nat. Bank Bldg., St. George, New Brighton, until July 11 (readvertisement) for furnishing materials and regulating, grading and paving with macadam on portions of several streets, in all about 24,250 sq. yds.

Brainerd, Minn.—Bids are wanted July 7 for paving with macadam of crushed rock, and a curbstone of granite or Kettle River sandstone, on Front St. Bids are also wanted for cement curb and gutter on Laurel St. R. K. Whiteley, City Engr.

Minneapolis, Minn.—The City Council has authorized the expenditure of approximately $60,000 for paving. The paving ordered being sandstone blocks on 6-in. concrete foundations for 3 streets, sandstone blocks on sand foundations for 2 streets; brick on 6-in. concrete for 2 streets, and macadam for 1 street.

Buffalo, N. Y.—Bids are wanted July 15 for paving a portion of Woodside Ave. Francis G. Ward, Comr. of Pub. Wks.

Jersey City, N. J.—Bids will be received by the Bd. of Street & Water Comrs. until July 8 for improving a portion of Garfield and Wilkinson Aves., requiring about 21,200 sq. yds. of Belgian pavement; also for improving a portion of Pavonia Ave., requiring about 1,822 sq. yds. of Belgian pavement. Geo. T. Bouton, Clk.

Napoleon, O.—Bids will be received by Usher Fisher, Village Clk., until July 22 for furnishing material and paving Perry St. and Oakwood Ave. (about 18,000 sq. yds.) with a vitrified brick or asphalt block on a stone foundation, or with asphalt block on present stone or sand foundation on Perry St. and on a crushed stone foundation on Oakwood Ave. C. N. Schwab, Engr.

Duluth, Minn.—W. B. Patton, City Engr., writes that bids will be received about July 14 for paving with sheet asphalt and also with Warren's bituminous macadam, about 20,000 sq. yds., on E. Superior St., from 8th Ave. E. to 16th Ave., E.

Galveston, Tex.—City Engr. C. G. Wells has submitted the following estimates for improving Tremont St.: pipe drain, which includes 1,900 ft. 36-in. and 1,425 ft. 30-in. drain, 50 catch basins and 1,920 ft. 12-in. connections, $13,122; brick paving, 16,183 sq. yds., 1,000,000 brick, removing old blocks, etc., $36,222.

Morgantown, W. Va.—See "Bridges."

Paterson, N. J.—Bids will be received by the Co. Bd. of Chosen Freeholders until July 7 for grading and macadamizing the Clove Road in Little Falls Township. Geo. W. Botbyl, Clk.

Bids will be received by the Road Com. of the Co. Bd. of Chosen Freeholders at Paterson, until July 7 for macadamizing the following roads: portions of Jane, North 3d and E. 26th Sts., Paterson Saw Mill Road, Wayne Township, and Broad St. and part of Montclair Ave., Pompton Lakes Borough. Jacob Geroe, Chmn.; Wm. L. Whitmore, Co. Engr., Rm. 29, Savings Institution Bldg., Paterson.

Darby, Pa.—Bids are wanted July 7 for grading and macadamizing portions of 3 avenues and a portion of Springfield Road. Address Wm. Simpson, Chmn. Highway Com., Box 82, Darby.

Mt. Pleasant, O.—Bids will be received by the Turnpike Comrs., care Jas. E. Finley, Mt. Pleasant, until July 23 for grading and macadamizing Mt. Pleasant Section and Long Run Free Turnpike.

Steubenville, O.—Bids will be received by the Co. Comrs. until July 22 for paving and curbing a road, about 5,200 ft. long and 28 to 30 ft. wide. C. M. Brown, Chmn.

Delaware, O.—Bids will be received by J. B. Taggart, Co. Surv., Delaware, until July 21 for constructing the Cryder and Hughes Road Improvement.

Chicago, Ill.—Bids are wanted July 8 for improving a portion of Blue Island Ave. by curbing and paving with brick. John A. May, Secy.

Cincinnati, O.—The contract for improving Augusta St. with granite has been awarded to F. H. Kirchner, Cincinnati, for $7,367.

Dayton, O.—Bids are wanted July 23 for paving with bituminous macadam, brick or sheet asphalt, furnishing and setting curbs on Maple St. Estimated quantities: 5,600 sq. yds. of paving, 3,650 lin. ft. straight curb, 80 lin. ft. circular curb, etc. Bids will also be received for paving with bituminous macadam or macadam, furnishing and setting curbs on Central Ave. Estimated quantities: 7,370 sq. yds. paving and 4,425 lin. ft. straight curb, 60 lin. ft. circular curb, etc. Robt. M. Ferguson, City Compt.

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until July 18 for furnishing material and improving portions of numerous streets, by grading, preparing the roadbed for the superstructure, setting granite curbing and laying a vitrified brick roadway, both on a concrete foundation. Said bids to include a 6-year guarantee. Hiram Phillips, Pres.

Long Island City, N. Y.—Bids will be received by Jos. Cassidy, Boro. Pres., until July 10 for furnishing and delivering to the Bureau of Highways 10,000 cu. yds. of broken stone and screenings of trap rock and limestone.

Brooklyn, N. Y.—Bids will be received by J. Edw. Swanstrom, Boro. Pres., until July 11 (extension of date) for regulating, grading and paving with asphalt (11,661 sq. yds) on portions of 4 streets. Bids will also be received for regulating, grading and paving 5,090 sq. yds. with granite on a sand foundation on Meserole and Waterbury Sts., 3,370 sq. yds. with macadam on Mermaid Ave., and for regulating and repaving 2,760 sq. yds. with Medina sandstone on a concrete foundation on High and South 3d Sts.

Des Moines, Ia.—Bids will be received by the Bd. of Pub. Wks. until July 21 for paving about 20,300 sq. yds. on Walnut St. with 1 course No. 1 vitrified brick on a concrete foundation, with Portland cement top filler. J. E. Stout, Chmn.

Lafayette, Ind.—Press reports state that Main St. is to be paved with asphalt.

Kensington, Md.—The Town Council has decided to issue $5,000 bonds for the purpose of constructing additional sidewalks and improving the streets.

South Bend, Ind.—Bids will be received July 8 by the Co-operative Investment Co., of South Bend, Edgar A. Stoll, Secy., for improvements on Bowman St. as follows: 19,082 sq. ft. cement walk, 3,896 lin. ft. cement curb, and 4,007 cu. yds. of excavation.

Chicago, Ill.—The South Side Streets & Alley Com. has decided to recommend the passage of an ordinance providing for the pavement of streets in the vicinity of 34th St. between Robey St. and South Western Boulevard. The improvement will cost $161,000.

Albany, N. Y.—Bids will be received by the Bd. of Contract & Supply until July 7 for grading and paving on portions of 3 streets with vitrified paving blocks; on a portion of Beaver St. with granite blocks and on a portion of Robin St. with vitrified fire clay paving blocks. Isidore Waschman, Clk.

Elgin, Ill.—A petition has been granted by the Bd. of Local Improv. for the paving of West Chicago St. with brick at an estimated cost of $18,000 to the city and $5,500 to street car company.

Fond du Lac, Wis.—F. A. Bartlett, City Clk., writes that it is proposed to repave Main St., probably with brick. Contracts will not be let until next spring. E. B. Parsons, City Engr. Probable cost, $40,000.

East Grand Forks, Minn.—Recorder Henry Harm writes that the City Council has extended the time for letting contracts for about 41,753 sq. yds. of paving and about 21,100 ft. of curbing until July 15, and will consider bids on cedar blocks, sandstone, solid granite macadam, or any other material. Plans and specifications for cedar block and solid granite macadam paving and for pine, Kettle River sandstone, solid granite curbing or combined curb and gutter, are on file in the office of the Mayor; parties bidding on other materials to furnish their own plans and specifications.

Bloomington, Ill.—An ordinance has been passed for brick pavement on Jefferson St. Elmer Folsom, City Engr.

Auburn, N. Y.—The Common Council on June 26 resolved to pave South and Dill Sts., in all about 17,200 sq. yds., with asphalt.

Beloit, Wis.—The Common Council has given notice that contracts are about to be let for grading, paving with vitrified brick, macadamizing and setting stone curbing on several streets. D. H. Foster, City Clk.

South Glens Falls, N. Y.—The Village Bd. is stated to have awarded to Perry S. Brackett at $3.37½ per sq. yd. the contract for paving a portion (about 1,000 yds.) of the river hill with granite block.

Saginaw, Mich.—The Bd. of Estimate is stated to have approved an issue of $5,000 east side street improvement bonds and $20,000 west side street improvement bonds.

Rochester, N. Y.—The Common Council on June 24 passed final ordinances for macadam pavement on Brunswick, Somerset and Tacoma Sts.; also for cement walks on Temple and Van Stallen Sts.

Avondale, Ala.—See "Railroads."

Allentown, Pa.—The Comrs. of Whitehall Township have decided to build a road on Helfrich Spring route from Allentown to W. Coplay. Estimated cost, $25,000.

Schenectady, N. Y.—An ordinance for grading, paving and curbing Devine St. has been adopted by the Common Council.

Cincinnati, O.—The County Comrs. have adopted a resolution asking Co. Engr. Krug to submit estimates for the improvement of Carthage Pike between Mitchell and Spring Grove Aves.

Trenton, N. J.—Local papers quote State Comr. of Pub. Roads Henry J. Budd as having stated that it is expected to build nearly 200 miles of State roads in New Jersey this year.

Camden, N. J.—The Bd. of Freeholders has rejected all bids opened June 25 for stoning Sandy Lane for a distance of 2.2 miles (the lowest bid being $16,419), and new bids will be opened July 9. Edw. S. Dobbs, Chmn. of Stone Road Com.

Lowell, Mass.—The Street Com. has voted to recommend the appropriation of $69,105 for the paving with asphalt and macadam of certain streets.

Watertown, N. Y.—The Bd. of Pub. Wks. on June 23 adopted a resolution for the paving of State St. from Smith block to Pleasant St. with bituminous macadam, at a total estimated cost of $42,113.

Niagara Falls, N. Y.—Local press reports state that plans are under consideration for extensive asphalt paving in the business portion of the city.

Tacoma, Wash.—Local press reports state that the Northwest Bridge Co., known as Mill & Tweeden, secured the contract for paving a portion of I St. with bituminous macadam for $37,409.

Indianapolis, Ind.—The contract for resurfacing with asphalt the roadway of a portion of Washington St. is stated to have been awarded to the Western Construction Co. at $6.46 per lin. ft.

Toronto, Ont.—Local press reports state that the following asphalt paving contracts have been awarded to the Forest City Paving Co., of London, Ont.: Fern Ave., $8,100; Phoebe St., $6,200; Spadina Ave., Queen to College, $43,400; Spadina Ave., Baldwin to College, east side, $8,000; west side, $5,900.

Washington, N. J.—The voters of Washington Township have voted to make application for 7 more miles of macadam roads, and authorized the Township Com. to borrow money to pay 10 per centum of the cost thereof.

Norwich, N. Y.—Plans and specifications have been prepared for paving old Lock St. with brick to a width of 22 ft. Estimated cost, $5,555 to $7,000.

Buffalo, N. Y.—The lowest bids opened June 26 for paving Bradley St. are reported to have been from the German Rock Asphalt Paving Co. at $8,730 for asphalt and from L. H. Gipp at $8,700 to $8,999 for brick, according to the kind desired.

E. St. Louis, Ill.—Bids are wanted July 8 for 25,200 sq. yds. of vitrified brick paving, cement grouted, on concrete foundation; 9,900 lin. ft. stone curbing, etc. L. L. Harper, Chmn. Bd. Local Improv.

Akron, O.—Bids are wanted July 12 for paving Byers Ave. with brick or block asphalt, about 3,000 sq. yds. J. W. Payne, City Engr.

Wilkesbarre, Pa.—This city has readvertised for bids, to be opened July 7, for resurfacing certain streets with asphalt. Fred. H. Gales, City Clk.

Chicago, Ill.—Bids are wanted July 9 for improving certain streets by curbing and brick paving. F. W. Blocki, Comr. of Pub. Wks.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until July 28 for improving a portion of Lincoln Ave. by grading, curbing and paving the roadway with asphalt. Geo. F. Holmes, Clk.

Ashland, Wis.—M. T. Dozer, City Engr., writes that the time for receiving bids for macadam paving has been extended to July 15.

St. Louis, Mo.—Bids will be received by Isaac S. Taylor, Dir. of Wks., until July 7 for lagoon grading, revetment and drains; also for 7,000 lin. ft. of macadam roads. Richard H. Phillips, Ch. Engr.

Detroit, Mich.—Bids for paving in several streets were opened June 24, the lowest in each case being as follows: Vinewood Ave., cedar, J. Mercer, $8,792, $1.43 per yd.; Forest Ave., brick, W. Lappin, $12,673, $1.91 per sq. yd.; Hastings St., brick, W. Lappin, $8,368, $1.98 per sq. yd.; 24th St., cedar, J. Porath, $12,854, $1.45 per sq. yd.; Humboldt Ave., cedar, J. Porath, $7,887, $1.56 per sq. yd.; Congress St., cedar, W. E. Linnane, $9,086, $1.53 per sq. yd.; Labrosse St., cedar, W. E. Linnane, $8,062, $1.49 per sq. yd.; St. Aubin Ave., cedar, Henry Merdian, $8,726, $1.42 per sq. yd.

Oshkosh, Wis.—The Council has awarded the contracts for paving Algoma St. to Harding, Nelson & Johnson, of Racine, for brick between Bond and Light Sts. at $2.39 per sq. yd., and to the Barber Asphalt Paving Co. for asphalt between Light and Jackson Sts. at $1.98 per sq. yd.

The Council has voted to issue street improvement bonds to the amount of $10,000.

Superior, Wis.—Local press reports state that the following bids were opened recently for repaving Tower Ave. with cedar blocks: *a*, setting curb, per ft.; *b*, oak lumber, per thousand; *c*, gravel, cu. yd.; *d*, white pine, thousand; *e*, hemlock, thousand; *f*, old plank, relaying, thousand; *g*, cedar, sq. yd.: Burke Bros., of Superior, *a* 8 cts., *b* $30, *c* 95 cts., *d* $26, *e* $21, *f* $6.50, *g* 80 cts.; P. McDonnell, of Duluth, *a* 15 cts.; *b* $35, *c* $1, *d* $23, *e* $18, *f* $7, *g* 79 cts. The contract is stated to have been awarded to Burke Bros., their total bid being estimated at about $55,000.

Elizabeth, N. J.—City Surv. W. H. Luster, Jr., writes that the following bids were opened June 16 for paving a portion of Fulton St.: A, J. R. Shanley, 26 Exchange Pl., Jersey City, $39,967; B, Jas. J. Poth, Elizabeth, $40,820; C, W. J. McCloud, Elizabeth, $43,331; D, Van Duzen & Oliver, New Brunswick, $46,930; E, Chas. Wagner, Jersey City, $42,383. For detail bids see accompanying table:

Bidders.	Specification blk., 21,625 sq. yds.	Curb reset, 10,000 ft.	New curb, 750 ft.	Curved corners.	Bridgestone.
A	$1.79	$.05	$.36	$1.00	$.95
B	1.83	.05	.40	.50	.90
C	1.94	.07	.40	.60	.75
D	2.10	.05	.35	.60	.70
E	1.90	.06	.40	.40	.80

St. Louis, Mo.—The following bids were opened June 10 for reconstructing Laclede Ave. from Grand Ave. to Kingshighway Boulev.:

Items and Quantities.	R. F. Conway & Co.	Parker-Washington Co. of W. Va.
Taking up old gutter and crosswalk pave., hauling, etc., per square of 100 ft., 671 ft.	$3.00	$3.00
Filling with new macadam, per square of 100 cu. ft., 145 cu. ft.	4.00	4.00
New Port. cement concrete, 6-in. deep, laid, per square of 100 ft., 671 ft.	9.20	9.00
New limestone curb, furnished and set, per lin. ft., 4,542 lin. ft.	.60	.70
Old curb reset, per ft., 3,634 lin. ft.	.10	.10
Rem. portions of roadway pave. above grade of found., per square of 100 ft., 2,291 ft.	3.00	2.50
Placing fine concrete 1-in. thick on portions of roadway having found. of old macadam, per square of 100 ft., 2,291 ft.	1.50	....
Vit. brick paving on base of sand, inclusive of expansion joint, per square of 100 ft., 2,962 ft.	18.66	16.50
Totals	$77,435	$70,212

Bids for the reconstruction of several other streets were opened at the same time and were as follows on the principal items: *a*, per lin. ft. for granite curbing 6 in. thick and 16 in. deep on concrete foundation; *b*, per square of 100 ft. for Portland cement concrete 6 in. deep, laid complete; *c*, per square of 100 ft. for vitrified brick paving laid on a base of sand; *d*, total:

Morgan St.—Parker-Washington Co., *a* $1.07, *b* $8.50, *c* $16.50, *d* $37,579; R. F. Conway & Co., *a* $1, *b* $9.20, *c* $16.02, *d* $37,365.

Lawton Ave.—R. F. Conway & Co., 50 cts. per ft. for 4-in. limestone curbing, *c* $18, *d* $39,132; Parker-Washington Co., 4-in. limestone curbing 65 cts., *c* $16.50, *d* $39,513; Gilsonite Const. Co., 55 cts. for 4-in. limestone curb, *c* $16.50, *d* $37,811.

Leonard Ave.—Morey Eng. & Const. Co., *a* $1.10, *b* $7, *c* $13.98, *d* $19,931; R. F. Conway & Co., *a* $1, *b* $9.20, *c* $16.02, *d* $22,611.

Cardinal Ave.—Fruin-Bambrick Const. Co., *a* $1.05, *b* $9, *c* $18.50, *d* $18,521; Morey Eng. & Const. Co., *a* $1.10, *b* $7, *c* $13.93, *d* $15,016; Parker-Washington Co., *a* $1.07, *b* $9, *c* $16.50, *d* $17,418; R. F. Conway & Co., *a* $1, *b* $9.20, *c* $16.02, *d* $17,092.

Compton Ave.—Morey Eng. & Const. Co., *a* $1.10, *b* $7, *c* $13.73, *d* $16,447; Fruin-Bambrick Const. Co., *a* $1.05, *b* $9, *c* $18.50, *d* $20,385; R. F. Conway & Co., *a* $1, *b* $9.20, *c* $16.02, *d* $18,816; Parker-Washington Co., *a* $1.07, *b* $9, *c* $16.50, *d* $19,180.

Boyle Ave.—R. F. Conway & Co., $1 per ft. for granitoid curb and gutter 3 ft. wide, *b* $9.20, *c* $18, *d* $15,017; Parker-Washington Co., $1.10 for granitoid curb and gutter, *b* $9, *c* $16.50, *d* $14,579.

Bridgeport, Conn.—City Clk. E. T. Buckingham writes that the following bids were opened June 23 for furnishing and laying about 8,500 sq. yds. of brick pavement: *a*, Mack block; *b*, Mack brick; *c*, Porter block; *d*, Porter brick; *e*, Syracuse brick: Silliman & Godfrey, Bridgeport, *a* $2.80, *b* $2.78, *c* $2.76, *d* $2.73, *e* $2.70; B. D. Pierce, Jr., Co., Bridgeport, *b* $2.85, *d* $2.80, *e* $2.80; C. W. Blakeslee & Sons, New Haven, Conn., *b* $2.79, *d* $2.72½, *e* $2.71½; Frank L. Pidgeon, Saugerties, N. Y., *a* $2.68, *b* $2.66 wire cut, *c* $2.25, *d* $2.46 wire cut (awarded), *e* $2.61 wire cut or straight edge.

New York, N. Y.—The following bids were opened June 30 by Jacob A. Cantor, Pres. Boro. of Manhattan, for asphalt block pavement on a concrete foundation: A, Hastings Pavement Co., 25 Broad St., B, Lake Erie Asphalt Block Co.; C, Continental Paving Co.:

Items and Quantities.	A.	B.	C.
Broadway, from 187th St. to Dyckman St. line.			
Asph. blk., 26,808 sq. yds.	$1.58	$2.30	$1.59
Concrete, 5,124 cu. yds.	6.00	5.50	6.40
New curb, 6,250 lin. ft.	.90	1.00	.95
Old curb, 1,250 lin. ft.	.40	.35	.45
Audubon Ave., from Kingsbridge Rd. to 173d St.			
Asph. blk., 8,768 sq. yds.	$1.79	$2.30	$1.59
Concrete, 1,636 cu. yds.	6.00	5.50	6.80
New curb, 1,500 lin. ft.	.90	1.00	.95
Old curb, 2,138 lin. ft.	.40	.35	.45

Albany, N. Y.—The following bids were opened June 28 at the office of Edw. A. Bond, State Engr. and Surveyor, for public highway improvements:

Road.	Bidder.	Local stone.
W. Henrietta, Monroe Co., 6.23 miles.	Whitmore, Rauber & Vicinus	$61,500
	Harry L. Smith	53,700
	Anderson, Thomas & Brown	52,200
	J. Dunfee & Co.	53,900
Scottsville, Monroe Co., 2.25 miles.	Wm. Fuller	21,800
	Brayer & Albraugh	19,369
	Harry L. Smith	21,375
	Anderson, Thomas & Brown	20,400
	John Dunfee & Co.	17,990
Catskill, Tompkins Co., 1.86 miles.	John Dunfee & Co.	13,600
Clifton, Monroe Co., 3.62 miles.	Brayer & Albraugh	30,988
	Chambers & Grady	34,786
	Casey & Murray	34,800
	Harry L. Smith	30,765
	John Dunfee & Co.	28,757
	Anderson, Thomas & Brown	33,400
Scottsville, Sec. 2, Monroe Co., 7.53 miles.	Brayer & Albraugh	68,485
	Swan & Murray	63,795
	Harry L. Smith	60,000
	John Dunfee & Co.	29,757
	Anderson, Thomas & Brown	55,555
	H. M. Cowles	29,500
Webster, Sec. 5, Monroe Co., 3.39 miles.	Casey & Murray	31,500
	Lauer & Hagaman	30,000
	Harry L. Smith	25,000
	John Dunfee & Co.	27,876
	Anderson, Thomas & Brown	32,000
	Thomas Holihan	29,410
Webster, Sec. 4, Monroe Co., 2.87 miles.	Casey & Murray	26,900
	H. N. Cowles	26,000
	Lauer & Hagaman	27,215
	Harry L. Smith	20,000
	John Dunfee & Co.	25,427
	Anderson, Thomas & Brown	29,100
	Thomas Holihan	26,390
Lestershire, Broome Co., 2.5 miles.	Crary Sons Co.	30,203
	John Dunfee & Co.	26,000

Rochester, N. Y., is given as the address of all bidders except the following: Harry L. Smith, Long Island City; Anderson, Thomas & Brown, Glens Falls; J. Dunfee & Co., Syracuse; Swan & Murray, Elmira; Crary Sons Co., New York.

Brooklyn, N. Y.—Bids were opened July 2 by the Boro. Pres. for asphalt paving on 18 streets. The largest bids were as follows: On Herkimer St. from Nostrand Ave. to Albany Ave.: A, Uvalde Asphalt Paving Co.; B, Century Construction Co.; C, Matthew T. Meagher; D, Cranford Co.; E, Brooklyn Alcatraz Co.; F, Interstate Paving Co.; G, Green River Asphalt Co.:

Bidders.	Asph., 11,070 sq. yds.	Conc., 1,860 cu. yds.	Old stone.	Curb: New, 5,150 lin. ft.	Curb: Old, 650 lin. ft.	Manhole covers, 33.
A	$1.35	$5.62	$.20	$.72	$.20	$3.00
B	1.92	5.40	.30	1.00	.35	21.00
C	1.50	5.50	.50	.75	.50	10.00
D	1.07	4.25	.25	.65	.25	5.00
E	1.25	4.50	.35	.75	.35	5.00
F	1.32	4.00	.30	.55	.45	4.00
G	1.30	4.75	.20	.65	.10	6.00

On Fourth Ave. from 40th St. to 60th St.:

Bidders.	Asph., 26,400 sq. yds.	Conc., 4,230 cu. yds.	Old stone.	Curb: New, 8,600 lin. ft.	Curb: Old, 1,000 lin. ft.	Manhole covers, 5.	Excav., 5,338 cu. yds.	Top soil, 9,609 cu. yds.	Conc. curb, 9,275 lin. ft.
A	$1.40	$4.40	$.20	$.68	$.20	$3	$.40	$1.25	$.50
B	1.82	5.20	.30	1.00	.35	21	.50	1.00	.90

POWER PLANTS, GAS AND ELECTRICITY.

Gallipolis, O.—Bids will be received by Geo. F. Bovie, City Clk., until July 15 for a 25-year franchise to construct and install an electric light plant, and furnish and sell electricity for power, heat and lighting purposes, and for furnishing the city for a period of 10 years with the following lights: 100 alternating current 6.6 amperes enclosed arc lamps; 10 3-glower 1.2 ampere 220-volts Nernst lamps; 50 16 c. p. incandescent lamps.

Wheaton, Ill.—See "Schools."

Santa Fe, N. M.—The Capitol Light & Power Co. has been incorporated, and according to report will develop the water power of Pecos River. A. R. Gibson, Pres. Consolidated Copper Co., is reported interested.

Manchester, O.—The citizens are stated to have voted to issue $7,000 bonds for an electric light plant.

Grafton, W. Va.—The Grafton Gas & Electric Light Co. is stated to have decided to expend about $10,000 in improvements.

Ft. Dodge, Ia.—The controlling interest in the Ft. Dodge Light & Power Co., including the Ft. Dodge St. Ry., is reported to have been sold to Healy Bros. & Kelleher, of Ft. Dodge. The property includes gas and electric light plants, and 3 miles of street railway. It is reported that the new management contemplates important improvements.

Lebanon, Tenn.—Engr. Granbery Jackson, of Tullahoma, Tenn., writes that the contract for electric light improvements has been awarded to J. E. Mott & Co., of Huntington, Ind., for $4,911. The contract includes 80 H.-P. boiler (Atlas), 75 H.-P. engine, Stillwell heater and feed pump, 50 Kw. alternator, 30 arc lamps with transformer, etc., installed and in operation.

Milwaukee, Wis.—See "Business Buildings."

San Jose, Cal.—The Globe Light & Power Co. has been incorporated, with a capital of $200,000, for the purpose of securing water rights and for building a power plant for the generation of electricity in the high Sierras. J. R. Curnaw and H. W. McComas, of San Jose, are among the directors.

Whittier, Cal.—J. C. Hiatt, of Whittier, is stated to have secured a franchise for the construction of a gas plant.

Altoona, Pa.—It is reported that the Mountain City Gas Co., recently incorporated, will construct a gas plant to cost $300,000.

Bloomsburg, Pa.—A franchise is stated to have been granted to the Irondale Electric Light, Heat & Power Co.

Hoopeston, Ill.—J. W. Tilford, representing the Chicago Building & Construction Co., 230 Lake St., Chicago, is reported interested in the construction of a gas plant.

Washington, D. C.—The Chesapeake & Potomac Telephone Co. is reported to have completed plans for about 7 miles of new conduits.

McRae, Ga.—See "Water."

Baker City, Ore.—The Consolidated Power Co. has been incorporated; capital, $100,000. Incorporators: Frank S. Baillie, H. S. Bowen and John L. Rand.

Waco, Tex.—See "Water."

Crockett, Tex.—The plant of the Crockett Light & Ice Co. is reported to have been destroyed by fire June 23.

St. Cloud, Minn.—The St. Cloud Light & Power Co. has been incorporated; capital, $32,000. Incorporators: Albert C. Cobb, J. O. P. Wheelwright and C. E. Johnson, of Minneapolis.

Westerly, R. I.—The citizens are reported to have voted in favor of municipal electric lighting.

Huntsville, Ala.—R. C. Brickell and associates are stated to have purchased the plant of the Huntsville Gas Light Co., and will make extensive improvements.

Allentown, Pa.—The power house of the Lehigh Valley Traction & Allentown Electric Light Co. is stated to have been destroyed by fire July 1. Two 550-H.-P. cross compound engines, 13 dynamos, an alternating machine and 7 boilers are also reported to be included in the loss.

Brooklyn, N. Y.—See "Public Buildings."

Newcastle, N. B.—Bids are wanted by R. T. D. Aitkin, Town Clk., until July 22 for an electric lighting system exclusive of boilers. Willis Chipman, Ch. Engr., 103 Bay St., Toronto, Ont.

Grafton, W. Va.—See "Water."

New Orleans, La.—The Dock Bd. is stated to have granted the New Orleans Lighting Co. permission to lay a gas pipe from some point on the banks of the river in the 1st District to a point on the Algiers side.

Charles City, Ia.—The Charles City Lighting & Htg. Co. has been incorporated; capital, $75,000. Geo. E. May, Pres.; H. V. Fusell, Secy.

Rockford, Ill.—J. A. Walker and Fred. K. Houston, of Rockford, are reported to have petitioned the Council for a franchise for a heating plant.

Rochester, N. Y.—The Bd. of Contract is stated to have awarded to the Rochester Gas & Electric Co. the contract to light the city for 5 years. The new contract price is at the rate of 21½ cts. a night each for lamps of 2,000 c. p., or $78.50 a lamp per yr., and 18¼ cts. a night each for 1,200 c. p. lamps, or $66.61 a lamp per yr. According to the figures of the City Engineer the contract price under the new contract is about $213,616 a yr.

ELECTRIC RAILWAYS.

Easton, N. Y.—The Bennington & Hoosic Falls Electric R. R. Co. is stated to have petitioned C. H. Dixon, Highway Comr. of Easton, for permission to construct and operate a surface railroad through Easton from Cambridge to Greenwich. Such a road would connect Hoosick Falls, Cambridge and Greenwich, and would be about 20 miles in length.

Geneva, O.—The Council is stated to have granted a franchise to the Cleveland, Painesville & Ashtabula Ry. Co.

New York, N. Y.—The certificate of the Bd. of Rapid Transit R. R. Comrs. granting permission to the Pennsylvania, New York & Long Island R. R. Co. to construct a tunnel railroad under the City of New York and under the East and North Rivers, and to maintain a terminal station on 32d St., Manhattan Boro., was filed with the Secretary of State June 26. It defines the route to be followed by the railroad and provides that electricity shall be the motive power. A. J. Cassatt, Pres. Robt. W. Groff, Secy.

Kansas City, Kan.—The Comrs. of Wyandotte Co. are stated to have granted a franchise to Willard E. Winner and other promoters of the Kansas City & Topeka Electric Ry. Co.

Grand Rapids, Mich.—H. F. Thomas, of Allegan, is reported interested in the construction of an electric railway between Grand Rapids and Kalamazoo.

Iola, Kan.—A charter is stated to have been granted to the Chanute & Iola Interurban Ry. Co. for a line 30 miles in length. M. T. Jones, Pres., Chanute.

Bloomsburg, Pa.—A franchise is stated to have been granted to the Bloomsburg & Millville Electric Ry. Co.

Portland, Ore.—A press report states that the Oregon & Portland City Ry. Co. will, in the near future, expend $5,000,000 upon a new system of trolley roads, the trunk line of which will extend from Portland to Spring Water, a distance of about 35 miles. W. H. Hurlburt, Pres., Portland.

Richmond, Va.—The plans and specifications of the Citizens' Rapid Transit Co. were filed with City Engr. Cutshaw. The plans are reported to include a viaduct to cost about $100,000.

Whately, Mass.—The Selectmen are stated to have granted the Greenfield, Deerfield & Northampton St. Ry. Co. a right of way through East Whately.

Columbus, O.—The Bd. of Pub. Wks. is stated to have granted a franchise to the Columbus, Newark & Eastern Traction Co.

Jacksonville, Fla.—Stone & Webster, of Boston, Mass., is stated to have purchased the street railway properties, and according to reports will make extensive improvements.

Huntington, W. Va.—The Camden Interstate Ry. Co. of this city is reported to have sold all its electric lines in this city, Central City, Ceredo and Kenova, W. Va., Catlettsburg and Ashland, Ky., and Ironton, and its electric light plants in Ironton, Ashland and Huntington, to John Graham and Edmund McCandish, of Newville, and John J. Henry, of Philadelphia.

Paducah, Ky.—A press report states that the Paducah St. Ry. & Light Co. will extend its line into Mechanicsburg across Island Creek; also construct a steel bridge across Island Creek.

Elizabeth, Pa.—The West Elizabeth & Dravosburg Bridge Co., recently incorporated, is reported to be considering the construction of an electric railway from the end of the Pittsburg Railways Company's Glassport division across the new bridge and up the Monongahela Valley to Monongahela City, a distance of 14 miles. Wm. T. Pierce, McKeesport; E. J. Askey, Pittsburg, and J. A. Pierce, Elizabeth, are among the incorporators.

Lebanon, Ill.—The City Council is stated to have under consideration an ordinance, granting a franchise to the St. Louis, O'Fallon & Lebanon Electric Ry. Co.

New York, N. Y.—A permit has been issued for the erection of a 2-story brick power house, to be erected by the Union Ry. Co., at 175th St. and Southern Boule.; cost, $20,000. Architect, A. V. Porter, 621 Bway.

Ft. Smith, Ark.—About 3 miles of electric street railway is now being located. In market for supplies. R. G. Hunt, Pres.

RAILROADS.

Dallas, Tex.—The International & Great Northern R. R. Co. has contracted with the citizens of Dallas to construct a branch line from Ft. Worth Division north of Italy to Dallas, a distance of 40 miles. It is also reported that the branch line which runs from Round Rock north to Georgetown is to be extended to Vernon, Tex., a distance of about 200 miles, where connection will be made with the Ft. Worth & Denver City and the Blackwell, Enid & Southwestern Railroads. J. D. Trammel, Ch. Engr., Palestine.

Phillips, Me.—The Madrid R. R. Co. is reported formed to construct a railroad in Phillips and in Township No. 6, Franklin Co. Fletcher Pope, Sidney G. Haley and others, all of Phillips, are the incorporators.

Cape Girardeau, Mo.—The Cape Girardeau & Chester R. R. Co. is reported incorporated, with a capital of $600,000. J. A. Hawkins, Wm. H. Bohnsach and Henry Hauenschild are among the incorporators.

Portales, N. M.—It is stated that the Atchison, Topeka & Santa Fe R. R. Co. will construct a line from Portales to Albuquerque. H. U. Mudge, Gen. Mgr., Topeka, Kan.

Carthage, Mo.—A charter has been granted to the Carthage & Western R. R. Co., of Carthage; capital, $270,000. The road is to be a Missouri Pacific extension and is to extend from Carthage to Asbury, a distance of 18 miles. Incorporators: Geo. J. Gould, New York, N. Y.; Russel Harding, of St. Louis, and others.

Blue Creek, W. Va.—It is reported that a line 22 miles long will be built by the Blue Creek & Belva Ry. Co. Preston Crowell, of Fairmont, is reported interested.

Buffalo, N. Y.—Local press reports state that the Lackawanna R. R. Co. will expend about $75,000 on improvements in Buffalo. C. J. Phillips, Div. Supt.

Manchester, Vt.—The Manchester, Dorset & Granville R. R. Co. is reported incorporated, with a capital of $350,000, to construct a steam railroad about 23 miles in length.

Baltimore, Md.—A press report states that the Suffolk & Carolina R. R. is to be changed from a narrow gauge line 35 miles long to a broad gauged system 75 miles long. An extension will be built to Edenton, N. C., and another to Elizabeth City, N. C. Wm. H. Bosley, Pres., Baltimore, Md. Henry Crocker, Supt., Suffolk, Va.

Chicago, Ill.—The Directors of the South Side Elevated R. R. Co. are reported to be considering the question of expending about $300,000 in the improvement of its line between 12th and 43d Sts.

Irondale, Ala.—The Mayor and Bd. of Aldermen are stated to have granted the Seaboard Air Line Ry. the right to lay tracks through the city, provided the company grade, macadamize and curb the avenues through which it will pass. J. M. Larr, Gen. Mgr., Portsmouth, Va.

New York, N. Y.—Bids are wanted July 21 by the Bd. of Rapid Transit R. R. Comrs. for the construction and operation for a period of 35 years, of the Bklyn. connection of the rapid transit railway, substantially as described in The Engineering Record of Feb. 9, 1901. This work includes loops at City Hall and the Battery, New York, and at Borough Hall, Bklyn., and tunneling under the East River. Alex. E. Orr, Pres.

Johnson City, Tenn.—The Ohio River & Charleston R. R., extending from Johnson City, Tenn., to Huntdale, N. C., is reported to have been sold to the Southern & Western R. R., of which Geo. L. Carter, of Bristol, is Pres. The purchasing company is reported to have authorized the issue of $600,000 bonds, with which to complete the construction already begun.

New Orleans, La.—H. H. Pearson, Jr., Pres. New Orleans Railways Co., is stated to have acquired the rights of the Orleans & Pontchartrain R. R. Co. and will at once construct the line.

Pittsburg, Pa.—Local press reports state that the Baltimore & Ohio R. R. Co. will expend about $1,100,000 on improvements in the Pittsburg district, including a $500,000 depot. J. M. Graham, Ch. Engr., Baltimore, Md.

Denver, Colo.—Bids will be received by the Denver & Northwestern R. R. Co. until July 10 for grading 18 miles of roadbed (divided into sections). T. J. Milner, Ch. Engr., Rm. 18, Evans Blk., Denver; S. M. Perry, Pres.

Lufkin, Tex.—An amended charter of the Texas & Louisiana R. R. Co. is reported to have been filed with the Secy. of State. The charter provides for building an extension of the road, which now runs from Lufkin, to Windham, on from Windham through the counties of Angelina, Nacogdoches, San Augustine, Jasper and Newton to the town of Newton, a distance of about 75 miles. E. A. Frost, Gen. Mgr., Lufkin.

PUBLIC BUILDINGS.

(See also Schools and Government Work.)

Winnipeg, Man.—Bids are wanted July 9 for plumbing the Post Office at Winnipeg. Fred Gelinas, Secy. Dept. of Pub. Wks., Ottawa, Ont.

New York, N. Y.—Bids are wanted July 10 for furnishing material and constructing lockers, ventilation and other work in the Metropolitan Museum of Art in Central Park. Wm. R. Wilcox, Park Comr.

Aitkin, Minn.—Bids will be received by the Bd. of Co. Comrs. until July 14 for heating and plumbing the Co. Court House. J. S. Campbell, Co. Aud.

Valley City, N. Dak.—Plans will be received by the Library Bd. until July 15 for a library, to cost about $15,000.

Walker, Minn.—Bids will be received by the Bd. of Co. Comrs. until July 15 for $30,000 bonds, the proceeds to be used to erect a court house. C. E. Griffith, Co. Aud.

Columbus, O.—Bids will be received by E. G. Carpenter, M. D., Secy. Bd. of Trus. of the Columbus State Hospital, until July 26 for furnishing material and erecting 2 buildings for the Hospital. It is reported that the buildings will cost about $40,000 each.

Hastings, Minn.—Leck & Prince, of Minneapolis, are stated to have secured the contract for erecting the wing additions to the Insane Asylums at Hastings and Anoka, to cost about $21,000 each.

Kalispell, Mont.—Contracts for the construction of Flathead Co. Court House and Jail are stated to have been awarded as follows: Buildings, to Hastie & Dougan, Spokane, Wash., $44,500; jail and cell work to the Irwin Hudson Co., of Portland, Ore., $6,770; and heating and plumbing to McIntosh Hardware Co., of Kalispell, $5,370.

St. Louis, Mo.—The Church of the Ascension is stated to have purchased a site on Cates and Goodfellow Aves. and will erect a new edifice on same, at a cost of about $50,000.

Elizabeth, N. J.—The lowest bid received June 25 for erecting the Union Co. Court House is stated to have been submitted by John H. Parker Co., New York, N. Y., for $534,750. This does not include the structural iron work, which is estimated to cost about $30,000 additional.

Baltimore, Md.—The contract for improvements to the First Baptist Church, Lafayette Ave. near Fremont, of which Rev. Curtis Lee Laws is pastor, is stated to have been awarded to Thos. L. Jones, 317 Clay St., for $60,000.

Kansas City, Mo.—It is stated that a church to cost about $60,000 is being planned by the Congregation of the Westminster Church. Rev. W. P. George, Pastor.

Cedar Falls, Ia.—The plans of W. A. Robinson, of Cedar Falls, are stated to have been accepted for the proposed Carnegie Library.

Sheboygan, Wis.—Contracts will probably soon be let for a new public library. For information apply to Francis Williams, of the Library Bd.

Baltimore, Md.—The contract for constructing an engine house on York Road has been awarded to John T. Buckley, 127 Richmond St., for $17,250.

Pueblo, Colo.—Patton & Miller, 115 Monroe St., Chicago, Ill., are reported to be the architects for the McClellan Public Library to be erected here, the funds having been provided by Andrew Carnegie. The building will be 2 stories high, and will cost $60,000.

San Jose, Cal.—The Bd. of Superv. are stated to have ordered plans prepared for a county building to be located in the rear of the Hall of Records, to cost $50,000.

Brooklyn, N. Y.—Plans have been filed for a 3-story brick parish building to be erected on Driggs Ave. and N. 6th St. for St. Vincent de Paul's Church, to cost $25,000. Architect, F. J. Berlenbach, 260 Graham Ave.

Paterson, N. J.—Local press reports state that bids recently received for restoring the City Hall have been rejected, the lowest being $85,149, and that new bids will be received July 16. Rudolph H. Matthies, Chmn. Pub. Bldgs. Com.

Eureka, Cal.—Bids will be received by the Carnegie Free Library Com. until July 21 for furnishing material and constructing the foundations and basement for Carnegie Free Library, including drainage and sewerage, and for furnishing material and erecting the superstructure, including all brick, stone, metal, mason, iron, terra cotta work, plumbing, etc. Geo. A. Kellogg, Secy.

Richmond, Va.—The Penitentiary Comn. has adopted the plans of P. Thornton Mayre, of Newport News, for a new cell building, to cost about $180,000. It will have 334 cells. Working plans will be ready about Aug. 1.

Washington, D. C.—It is stated that a new edifice is to be erected on 16th and Madison Sts., for the Foundry M. E. Church, to cost about $150,000. Rev. Luther B. Wilson, Chmn. Bldg. Com.

St. Louis, Mo.—The contract for erecting the Art Palace, the permanent structure at the World's Fair, is reported to have been awarded to the Goldie Construction Co. for $945,127.50. The building is designed to become a Louisiana Purchase Museum after the close of the fair.

153 and 155 E 118th St, br stores & tenemt; c, $45,000; o, Max Gold; a, Horenburger & Straub.
5th Ave & 127th St, br and stone club; c, $80,000; o, Columbia Club; a, Oscar Lowinson.
Jerome & Bernside Aves, br stores & tenemt; c, $40,000; o, Asher L Smith; a, John Hauser.
Collister, Hubert, Laight & Hudson Sts, 3 sty side and rear extension to br stable; c, $45,000; o, American Express Co; a, Chas W. Romeyn.

DWELLINGS.

Darien, Conn.—Howells & Stokes, 100 William St., are stated to have completed plans for a new country home for Anson Phelps Stokes, of New York, N. Y., to be erected on Collender's Point, Darien, Conn. The estimated cost of the mansion and various buildings to be erected on the place will be $250,000. This also includes the purchase price on the property.

Milton, Mass.—Mr. Milliken has begun the foundation for a house on Brush Hill Road, to cost about $200,000; contract for construction not yet let. W. H. Besarick, of Boston, Archt.

Detroit, Mich.—A 4-story flat is to be built on Joy St. for Dr. Newton. Cost, $30,000.

Kansas City, Mo.—F. E. Parker, 622 Whitney Bldg., has prepared plans for a $15,000 brick dwelling to be erected at Lydia and 10th Sts. Owner, E. S. Youmans.

NEW YORK CITY.

Permits for the following buildings have been issued: c, signifies cost; o, owner; a, architect; m, mason; cr, carpenter; and b, builder.

Rivington & Norfolk Sts, br tenemt; c, $45,000; o, Goodman Bros; a, Alfred E Badt.
38 E 40th St, br and stone dwelg; c, $25,000; o, Wm C Sheldon; a, Ernest Flagg.
342 & 344 E 15th St, br and stone tenemt; c, $42,000; o, Weinstein & Simon; a, Geo F Pelham.
96th St & 5th Ave, br and stone dwelg; c, $30,000; o, Irwin A Powell; a, York & Sawyer.
Brown Pl and 135th St, 3 br tenemts; c, $66,000 all; o, Walter A Dick; a, C F Kruse.
Railroad Ave & 158th St, 2 br and stone flats; c, $44,000 all; o, Fritz Selje; a, H T Howell.
106 E 57th St, rear extension to br dwelg; c, $20,000; o, Jas W Taylor; a, Marshall R Grimes.

SCHOOLS.

Cleveland, O.—Bids will be received by the Bd. of Educ. until July 23 for furnishing material and erecting an addition to Sibley School, work to include mason, cut stone, iron and steel, galvanized iron and tin work, fireproofing, ventilating and heating, plumbing, gasfitting, sewering, etc. Starr Cadwallader, School Dir.

Camden, N. J.—The City Council is stated to have passed an ordinance authorizing the issue of $50,000 bonds for the purpose of erecting one school and repairing other school buildings.

New York, N. Y.—The Bd. of Educ. is stated to have approved the following contracts: To the Commercial Construction Co., 1 Madison Ave., installing electric light wiring in the new High School of Commerce, Boro. of Manhattan, $27,315; Hartman & Horgan, 287 4th Ave., N. Y. City, alterations to School No. 106, Boro. of Brooklyn, $34,843; and Blake & Williams, 362 W. Bway., N. Y. City, for installing ventilating and heating apparatus in School No. 140, Boro. of Brooklyn, $18,782.

Scranton, Pa.—The Bd. of Control is stated to have decided to erect a $65,000 high school.

West Homestead, Pa.—Hall & Morgan, of Homestead, are stated to have secured the contract for erecting a school in West Homestead for $40,000.

Bellevue, Pa.—B. A. Groah & Co., Ltd., 409 Market St., Pittsburg, are stated to have secured the contract for erecting the 3d Ward school for $39,064.

Braddock, Pa.—E. J. Carlisle & Co., 700 Lewis Blk., are stated to have prepared plans for an $85,000 school.

Elwood City, Pa.—R. G. Brown is stated to have secured the contract for erecting a school for $24,774.

Amherst, Mass.—Amherst College is reported to have received a gift of $65,000 to erect an observatory for the astronomical department.

Pocahontas, Ia.—W. J. Ziterell, of Webster City, is stated to have secured the contract for erecting a school for $16,475.

Baltimore, Md.—The contract for constructing an addition to School No. 54 has been awarded to John T. Buckley, 127 Richmond St., at $17,590.

St. Charles, Ill.—Jenney & Mundle, N. Y. Life Bldg., Chicago, are stated to have prepared plans for the Rural Home and School for Boys, to be erected about 2½ miles n. w. of St. Charles. The buildings will consist of 14 double 2-story cottages for the boys, 4 cottages for the teachers, a 3-story administration and school building, a 1-story manual training school, assembly hall, dining-room, gymnasium, power house, and stables. The buildings will all be of brick and stone, with slate roofs, and will cost probably $250,000.

Wheaton, Ill.—The Bd. of Trus. of Wheaton College is stated to have voted to erect a central heat, light and water plant and a new industrial building, to cost about $40,000.

Carterville, Mo.—The citizens are stated to have voted to issue $21,000 school bonds.

Bloomington, Ind.—John D. Rockefeller is stated to have presented to the Indiana Univ. $30,000 for the erection of a building for social and religious purposes.

New London, Conn.—The lowest bid received for erecting the Central School is stated to have been submitted by Carpenter & Williams, of Norwich, for $58,500.

Ann Arbor, Mich.—The Phi Delta Theta Fraternity is stated to have purchased a site on S. University and Washtenaw Aves. and will erect on same a $25,000 building.

St. Paul, Minn.—Bids will be received by the Bd. of School Inspectors until July 16 for furnishing material and erecting the superstructure of the C. K. Davis School and additions to the Grant, Harrison and Baker Schools.

Indianapolis, Ind.—Bids will be received by the Bd. of School Comrs. until July 8 for steam heating, plumbing and sewerage for School No. 33. J. E. Cleland, Bus. Dir.

Peabody, Mass.—See "Water."

Ann Arbor, Mich.—Bids will be received by the Bd. of Regents of the Univ. of Michigan until July 15 for erecting a Psychopathic Ward at University Hospital in Ann Arbor. Jas. H. Wade, Secy. Bd.

Trenton, N. J.—Bids will be received by the Bd. of Educ. of Hamilton Township at the office of John Sykes, 111 E. State St., Trenton, until July 7 for erecting a school in Groveville. W. C. Rockhill Hart, Dist. Clk.

Albion, N. Y.—It is stated that plans are being prepared for a high school.

Richmond, Cal.—The citizens are stated to have voted to issue $15,000 bonds for a school.

Yonkers, N. Y.—Lynch & Larkin are stated to have secured the contract for erecting an addition to the high school for $45,950.

Bolivar, Pa.—E. M. Lockhard, of Indiana, Pa., is stated to have secured the contract for erecting a school on Lincoln Ave. for $20,000.

Portland, Me.—Bids will be received by Frederic E. Boothby, Chmn. Com. on Pub. Bldgs., until July 7 (readvertisement) for alterations and additions to primary school at Stevens Ave. and Concord St. and for erecting an addition to primary school at Allen's Corner. F. H. & E. F. Fassett, Archts., 93 Exchange Pl.

W. Springfield, Mass.—Bids will be received by C. E. Brockway, Secy. Bldg. Com., until July 11 for erecting, plumbing, heating and ventilating a 4-room brick school on Riverdale Ave.

Philadelphia, Pa.—Cope & Stewardson, 320 Walnut St., are stated to have completed plans for a 3-story engineering building, to be erected on the grounds of the Univ. of Pennsylvania. It will be largely of steel and of slow burning construction.

Sandusky, O.—Bids will be received by Chas. Kubach, Clk. Bd. of Educ., until July 25 for erecting a 4-room addition to the 9th Ward School.

Okmulgee, Ind. Ter.—Bids are wanted for $20,000 school bonds. Address Valdo Smith, Recorder.

Chicago, Ill.—Bids are wanted by the Bd. of Educ. until July 11 for work in the Wabansia School as follows: Masonry, cut stone, sheet metal, steel ceilings, composition roofing, structural iron, fireproofing, steam heating, heat regulation, ventilation, plumbing, gas fitting, sewerage, electric work, etc. W. B. Mundie, Archt., N. Y. Life Bldg., Chicago.

Dowagiac, Mich.—Bids will be received by the Bd. of Educ. until July 10 for erecting a 12-room school. F. H. Codding, Secy. Bd. Educ.

Tippecanoe City, O.—Bids will be received until Aug. 2 by C. H. Allen, Clk. of Bethel Township, for erecting a brick school in Dist. No. 3, to be known as Fairview School.

Castle City, Utah.—Bids will be received by the School Bd. until July 11 for erecting a school. Address W. D. MacLean, Secy.

Bangor, Me.—Wm. N. Sawyer is stated to have secured the contract for erecting a school at 1st and Union Sts. for $18,500.

STREET CLEANING AND GARBAGE DISPOSAL.

Racine, Wis.—The city officials have under consideration a proposition for the construction of a garbage crematory.

Johnstown, Pa.—Bids are wanted July 15 for furnishing a street sweeping machine. Geo. E. Hamilton, City Clk.

San Juan, Porto Rico.—The Dixon Garbage Crematory Co., Toledo, O., has been awarded the contract for constructing a garbage crematory at the United States Army Post at this point.

Newark, N. J.—Bids are wanted July 17 for the collection and disposal of garbage, paper, ashes and rubbish for a term of 5 years, as advertised in The Engineering Record.

Lawrence, Mass.—The Bd. of Health has received a proposition from the U. S. Garbage Reduction Co. for the collection and disposal of the city's garbage for $30,000 a year.

Sheboygan, Wis.—The question of garbage disposal is said to be under consideration.

GOVERNMENT WORK.

San Francisco, Cal.—Bids are wanted Aug. 9 for constructing a 1-story brick and steel building 300x100 ft., at the Navy Yard, Mare Island, Cal. Plans and specifications will be furnished by the Commandant of the navy yard upon deposit of $15 to secure their return. Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C.

Ft. Robinson, Neb.—Bids are wanted July 23 for furnishing and installing a steam heating plant in the commanding officer's quarters and in the 5 double sets of officers' quarters at Ft. Robinson. Address J. W. Pullman, Ch. Q. M., Omaha, Neb.

Ft. Hancock, N. J.—Bids are wanted July 19 for constructing, heating, plumbing and gas piping addition to hospital and constructing, plumbing and gas piping dead house at this post. Address D. F. Craig, Q. M.

Joliet, Ill.—Bids are wanted July 29 at the Treasury Dept., Washington, D. C., for furnishing the low pressure steam heating apparatus, etc., for the U. S Post Office at Joliet, as advertised in The Engineering Record.

Norfolk, Va.—The following bids were opened June 21 at the Bureau of Yards & Docks, Navy Dept., Washington, D. C., for a 1-story fireproof building 60x240 ft. at the Navy Yard, Norfolk: J. H. Brinson, Hampton, Va., $25,741; Frank Pidgeon, Saugerties, N. Y., $28,792; J. W. Talliflerro & Co., Brooklyn, N. Y., $26,387; Penn Bridge Co., Beaver Falls, Pa., $25,867; Grant Wilkins, Atlanta, Ga., $28,500.

Ft. Totten, N. Y.—The R. G. Packard Co., 130 Pearl St., New York City, on June 13 bid 17 cts. per cu. yd. for dredging. The address of this company was incorrectly given last week as Providence, R. I.

Freeport, Ill.—Bids are wanted Aug. 13 at the Treasury Dept., Washington, D. C., for furnishing the steam heating apparatus complete for the U. S. Post Office at Freeport, as advertised in The Engineering Record.

Ft. Totten, N. Y.—Bids are wanted at the office of the Quartermaster until Aug. 1 for constructing addition to Guard House at this post, as advertised in The Engineering Record.

Wilkesbarre, Pa.—The contract for constructing the U. S. Post Office at Wilkesbarre has been awarded to Cramp & Co., Philadelphia, for $88,777.

Washington, D. C.—The Senate on June 25 passed a bill providing for a building for the Department of Agriculture to be constructed in accordance with plans already adopted. The limit of cost for this building is $2,500,000, which is to include heating and ventilating apparatus, elevators and approaches.

MISCELLANEOUS.

Brooklyn, N. Y.—Bids are wanted July 11 for furnishing material and repairing the wooden pier with appurtenances at the foot of Noble St., East River, Brooklyn. McDougall Hawkes, Comr. of Docks, N. Y. City.

Pittsburg, Pa.—The Council has passed ordinances authorizing the letting of contracts for improvements in the parks aggregating $169,000.

Portland, Ore.—E. T. C. Stevens, Clk. Port of Portland Bd., writes that the following bids were opened June 26 for constructing a floating wooden drydock of 5 sections, according to plans and specifications prepared by Jas. E. Blackwell, Consulting Engr., Dexter Horton Bldg., Seattle, Wash.: Jos. Pacquet, Portland, $195,000; R. Wakefield, Portland, $198,000; J. B. Bridges, Portland, $199,750; J. E. Bennet, Portland, $204,000.

Minneapolis, Minn.—Local press reports state that the Supreme Court has decided that Mayor Ames must sign the $150,000 permanent improvement bonds authorized by the last Legislature.

Buffalo, N. Y.—The Councilmen have adopted the resolution of the Aldermen in favor of dredging work in Buffalo River at a cost of $12,000, in the ship canal at a cost of $7,500, and in the Peck slip at a cost of $400; total cost, $19,900.

Boston, Mass.—The following bids were opened June 26 by the Harbor & Land Comrs. for dredging an anchorage basin in Boston Harbor 1,000 ft. wide and about 1 mile long, the work to be divided into 4 sections, each containing about 650,000 cu. yds: *a*, Section 1, items 1, 2 and 3 respectively; *b*, Section 2; *c*, Section 3; *d*, Section 4. Prices given are per cu. yd.: Eastern Dredging Co., 247 Atlantic Ave., and New England Dredging Co., 185 Summer St., *a*, 16.3 cts., 19.3 cts. and 18.5 cts. (awarded); *b*, 19.3 cts.; *d*, 16.3 cts.; G. H. Breymann & Bros., Toledo, O., *a*, 15 cts., 15 cts. and 30 cts.; *b*, 15 cts. (awarded); *c*, 15½ cts. (awarded); *d*, 16 cts. (awarded); Bay State Dredging Co., 19 High St., Boston, *a*, 19¾ cts., 19½ cts., and 20 cts.; Morris Cummings Dredging Co., 17 State St., N. Y., *a*, 16 cts., item 1; *b*, 17 cts.; *c*, 16.7 cts.; *d*, 16½ cts.; Chas. M. Cole, Fall River, Mass., *b*, 20½ cts.; *c*, 24 cts.; J. S. Packard Dredging Co., 425 Angell St., Providence, R. I., *b*, 24 cts.; Daly & Hannan Dredging Co., Ogdensburg, N. Y., *b*, 25.9 cts.; *c*, 25.9 cts.

Southold, L. I., N. Y.—Bids will be received by Chas. S. Boyd, State Supt. of Pub. Wks., at Albany, until July 10 for constructing a sea-wall between the Sound and Orient Harbor, between the villages of East Marion and Orient, in the town of Southold.

Kansas City, Mo.—The Admiral Boulevard and Budd Park bonds, amounting to $140,000, were sold recently.

Boston, Mass.—The Governor has signed the bill providing for the construction of a tunnel and additional subways in Boston.

Port Adelaide, South Australia.—Bids will be received at the office of the Engineer-in-Chief, Adelaide, South Australia, until Sept. 30 for constructing a harbor at Light's Passage, Port Adelaide. Drawings and specifications may be obtained on the payment of £5 per set, which amount will be returned to unsuccessful bidders who have sent in a bona fide bid, on return of the documents in good condition within one week from date of notice of non-acceptance of bid. Bids are to be accompanied by an Adelaide Bank deposit receipt of £100, or a cheque on an Adelaide bank for a like amount, marked "Good for 1 week," in favor of the Engineer-in-Chief., H. Allerdale Grainger, Agent General for Australia, 1, Crosby Sq., London. For estimated quantities see page 431, The Engineering Record of May 3.

NEW INDUSTRIAL PLANTS.

The Block-Pollak Iron Co., Cincinnati, O., is figuring on building a steel addition to its forge building at Carthage, O., and installing a 10-ton steam hammer and two smaller hammers for forging purposes.

The Denver, Colo., Sugar, Land & Irrigation Co. will build a beet-sugar factory to have a daily capacity of 350 tons and to allow for doubling this capacity. Wm. C. Johnston, Pres.

F. Sitterding, 609-625 St. James St., Richmond, Va., expects to build a planing mill, sash, door and blind factory next fall. The steam power plant of 100 H.-P. will probably consist of new boilers and engine in addition to the present 40-H.-P. plant.

The Louisville, Ky., Lead & Color Co. has received bids for a 4-story and basement, 60x160-ft. paint factory, which will be equipped with a power plant, sprinkling system and paint machinery. Kenneth McDonald & J. F. Sheblessy, Louisville, Ky., architects.

The Meyer Furnace Co., Peoria, Ill., will erect a new factory to replace that recently burned, and install a 17½ and a 7-H.-P. motor.

The Ridgway, Pa., Machine Tool Co. will erect the following brick and steel building: 75x225-ft. erecting shop; machine shop, 187½-ft. square; foundry, 150 ft. square; 75x150-ft. pattern building; 37½x75-ft. forge shop, and power house, 37½ ft. square.

The Stark Brewing Co., Canton, O., will erect a 20,000-bbl. brewery on a 140x200-ft. plot.

John Gwynn, Yorktown, Ia., is erecting a 10,000-bu. elevator and is in the market for a 10-H.-P. gasoline engine.

The Allen & Currey Mfg. Co., Ltd., Shreveport, La., contemplate erecting a 2-story, 70x140-ft. planing mill and sash and door factory, together with a boiler house, shaving vault and dry kiln. A 150-H.-P. engine and probably a battery of two boilers will be installed.

J. J. Hollaway, Clem, Ga., is interested in forming a company with a capital of $20,000 to erect an oil mill and ginnery.

The New Process Steel Co., Homestead, Pa., contemplates erecting a blast furnace having a daily capacity of 500 tons; three steel-casting foundries, one for machine-molded and small castings, the second for rolls, rolling mill castings and forge blooms, and the third for locomotive, electrical and ship castings; a forge shop, and a machine shop.

The Horseshoe Mining Co., Deadwood, S. D., is receiving bids for the erection of a 350 stamp wet crushing cyanide mill to be located at Pluma, S. D., to have a daily capacity of 1,250 tons. The steam power plant will include engines of about 1,000 H.-P., boilers, air compressors, pumps, etc.

The Peters & Bradley Mill Co., Knoxville, Tenn., will rebuild a 3-story, 36x56-ft. building and install a 100-bbl. flour mill and a power plant of about 60 H.-P.

BUSINESS NOTES.

Buff & Buff, Jamaica Plain, Mass., have removed their Boston office to larger quarters at 27 School St. G. G. Leddes is the Boston sales agent.

The West Virginia Bridge & Construction Co., Wheeling, W. Va., is erecting a plant with a capacity of 1,000 tons per month for the construction of steel factory and office buildings, bridges, viaducts, tanks, etc., which it expects to have in operation by Oct. 1, 1902. The officers are Edward Hazlett, Pres.; Geo. A. Laughlin, Vice-Pres.; G. E. Wincher, Secy. and Treas.; J. H. Barrett, Gen. Mgr.

The Crocker-Wheeler Co., Ampere, N. J., manufacturers of direct-current machinery, report the following among recent orders: Standard Steel Works, Burnham, Pa., 2 200-Kw. generators; James Cooper Mfg. Co., Montreal, Can., 55-Kw. generator; Buda Foundry & Mfg. Co., Harvey, Ill., 240-Kw. generator; Whitehall Portland Cement Co., Cementon, Pa., 85-H.-P. motor; Woodward & Lothrop, Washington, D. C., a 200-Kw., 2 150-Kw. and a 75-Kw. generator; Sparrell Print, Boston, Mass., 14 motors, 3 to 10 H.-P.; Tidewater Steel Co., Chester, Pa., 250-Kw generator; Minot, N. D., Light & Telephone Co., 90-Kw. generator; Armour & Co., East St. Louis, Ill., four 50-H.-P. motors and a 75.-H-P. motor; Green Engine & Machine Co., Harrison, N. J., four 35-H.-P. motors; Descubridora Mining & Smelting Co., Mexico, 4 20-H.-P. motors; Moline Malleable Iron Co., St. Charles, Ill., 90-Kw. generator and 11 motors aggregating 125 H.-P.; Pennsylvania Sugar Refinery, Philadelphia, Pa., 14 motors, 3 to 15 H.-P.; Fretz Umbrella Works, Philadelphia, Pa., 80 motors in small sizes; Lake Shore & Michigan Southern shops, Collinwood, O., 11 motors aggregating 200 H.-P.

The American Steel & Wire Co., Chicago, reports receiving the following awards at the South Carolina Inter-State and West Indian Exposition, each medal being the highest award in its class: Gold medals for merchants iron and steel, cold-drawn steel shafting, horse and mule shoes, wire nails, rail bonds, wire rope, machinery and appliances for drawing wire, springs and spring wire, copper wire, iron and steel wire, aluminum wire. Silver medals for bicycle and automobile spokes, rolled wagon skeins, underground and overhead wires and cables, metallurgy of zinc. Bronze medals for music wire, coal and coke, bale ties, chemicals and colors. Diploma of merit for installation in Commerce Building.

The San Bernardino, Cal., Gas & Electric Co. has recently purchased additional power plant from the Ball Engine Co., Erie, Pa., and Stearns & Foster, Cincinnati, O., are installing an electric plant to consist of a Bullock generator direct-connected to a Ball engine.

The Continental Iron Works, Brooklyn, have recently increased their electric equipment by putting in 11 Westinghouse induction motors, a two-phase alternator and switchboard. The alternating current apparatus will be used almost exclusively in the works after this installation is in operation.

A series of articles on American Art Industries is running in the New York Tribune, and the third paper of the set, published on June 15, is an interesting account of the development and extent of horticultural architecture, as exemplified in the business of the Lord & Burnham Co., Irvington, N. Y.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union.

Standard Cement Specifications.

At the recent meeting of the American Section of the International Association for Testing Materials a number of important subjects relating to the uniform determination of qualifications for materials used in engineering construction were well discussed, and among the topics the testing of cements stands at least equal with the others in prominence. The matter of uniform specifications governing the physical or other qualities to be required by civil engineers from the manufacturers of cements is one of unusual gravity for several reasons. Among them is the fact that the manufacture of Portland cements of the best quality has been extended with remarkable rapidity during the past half dozen years, so that at the present time the annual production of cement mills surpasses any limit which the most active imagination would have suggested at the beginning of this period. This obviously means that the use of Portland cement has enormously increased and that civil engineers are making rapidly widening applications of concrete and other classes of masonry in which the resistance and endurance of the completed structure depends wholly upon the cement employed.

In the earlier days of the manufacture of Portland cements, some of their characteristics were not well understood and many of the specification requirements assumed their various and varying features for the reason that their engineer authors were ill acquainted with the things to which those specifications applied. It was absolutely imperative that they should protect their works by those requirements which in their judgment would result in securing a good quality of cement even though their knowledge of that material was neither complete nor exact. It is not surprising under such circumstances that there was produced an abundant crop of all sorts of cement specifications, some, or possibly most, of which were on the whole fairly good, but with a constantly increasing variety of requirements, with uniformity nowhere in sight, calculated to distress the cement manufacturer in a certain and most effective manner. Such a condition of things is perplexing to all concerned; it is advantageous neither to the engineer nor to the manufacturer, nor to any one else, and it is time that the whole matter of cement testing and cement specifications should be put upon a rational and uniform basis. This has been done in connection with the products of the iron and steel mills, at least substantially so, and there is no valid reason why equally sensible and useful procedures should not be employed to determine the excellence of the products of the cement mills, or their adaptability to definite classes of engineering construction.

The processes required to produce prescribed results in cement manufacture with given and suitable raw materials are now well understood and under control. The weak or other unsatisfactory features of cement which are most likely to develop and work injury to any given class of engineering construction can now be anticipated with such reasonable certainty as to enable every competent civil engineer to specify in an effective and fair manner for any prescribed work. With these conditions existing it would seem to be a comparatively simple matter to arrange a set of standard cement specifications sufficiently comprehensive to meet all the demands of at least ordinary construction and sufficiently flexible in those features where it is necessary to satisfy either what may be called the local features of cement manufacture or the special conditions found in connection with different classes of structures. These standard specifications should obviously include such physical features as fineness of grinding, possibly specific weight, but certainly tests for tensile and compression resistances, change of volume in setting, endurance, especially in sea water, and other characteristics imperative for a resisting and enduring cement.

The great difficulty to be encountered in bringing about these desirable results lies first in determining what agent or body shall undertake to secure them, and second, in harmonizing the different interests concerned, both on the part of the user and the producer, so as to attain results which will be respected by all concerned. The handling of such a question involves tact and a thorough understanding of all the elements of the problem. The meeting of the American Section of the International Association for Testing Materials held at Atlantic City appeared to develop a feeling that it would be wise to await the action of the Committee of the American Society of Civil Engineers now having under consideration the same subject of cement testing and affiliated matters. This is undoubtedly the correct attitude. There may possibly be some doubt as to the propriety of the Society taking up for investigation and decision professional questions properly lying within the practice of its members, but there can be no doubt whatever as to the advantage which would accrue from certain general recommendations bearing upon the uniform testing of cements or general standard requirements for that material. Mature recommendations emanating from a committee of that body after deliberate investigations and consideration would undoubtedly be respected by both civil engineers and manufacturers. The report of such a committee would at least form a basis on which both civil engineers and manufacturers might meet and agree as to working standard specifications which could with great advantage displace the almost infinity of specification requirements now existing. It is perfectly practicable to secure these ends; there is required only a moderately concreted action on the part of those interested, with ample opportunity for the consideration and discussion of requirements which have, in the manner indicated, assumed manifold character and multiplicity of values.

In such standard specifications there should be prescribed tests for cements and cement mortars to determine as nearly as practicable just those qualities required in the actual duty of various grades of masonry. Short time tests, as at the end of twenty-four hours, should be given only such limited significance as properly belongs to them. Nor should erratically exacting tests for checking be prescribed in which cement pats are subjected to conditions that neither bear any resemblance whatever to experience in actual construction nor disclose qualities which, so far as known, have any discoverable relation to duties to be performed in the finished structure. This subject of standard specifications for cements is earnestly commended to the consideration of both engineers and manufacturers.

The New Power Plant of the Des Moines City Railway Co.

Thirty-five years ago, a pair of bay mules hauled a shiny yellow car with canopy roof along a twelve-block track in Des Moines and thus inaugurated street railway traffic in a city which to-day possesses a system of unusual interest. The early line was owned by a Dr. Turner, who was a little later joined by Mr. J. S. Polk. Other roads came into existence, some of them electric, others steam and gasoline. The need of uniting them to improve the service and reduce expenses finally became so evident that the Des Moines City Railway Company was organized about 1888 to take over all the properties. Mr. J. S. Polk, then as now the president and leading stockholder of the company, recognized the advantages of electric traction, and the road was one of the first west of the Mississippi to put in a complete electric equipment.

This power equipment was extended from time to time until the equipment included its present outfit of ten 20x6-foot and six 18x5-foot horizontal return tubular boilers, a 200-horse-power vertical boiler, a 22x48-inch and a 30x60-inch Lane & Bodley Corliss engine and a 20x42-inch Sioux City Corliss engine. These engines drive a 200-kilowatt Siemens & Halske generator, a 150-kilowatt General Electric generator and a line shaft to which eleven 45-kilowatt Thomson-Houston dynamos are belted. Two Westinghouse compound engines from the Omaha Exposition are set up in an annex to the engine room and are both belted to a General Electric three bearing generator of about 200 kilowatts capacity, a form of drive which is not very often encountered, even in old-time plants

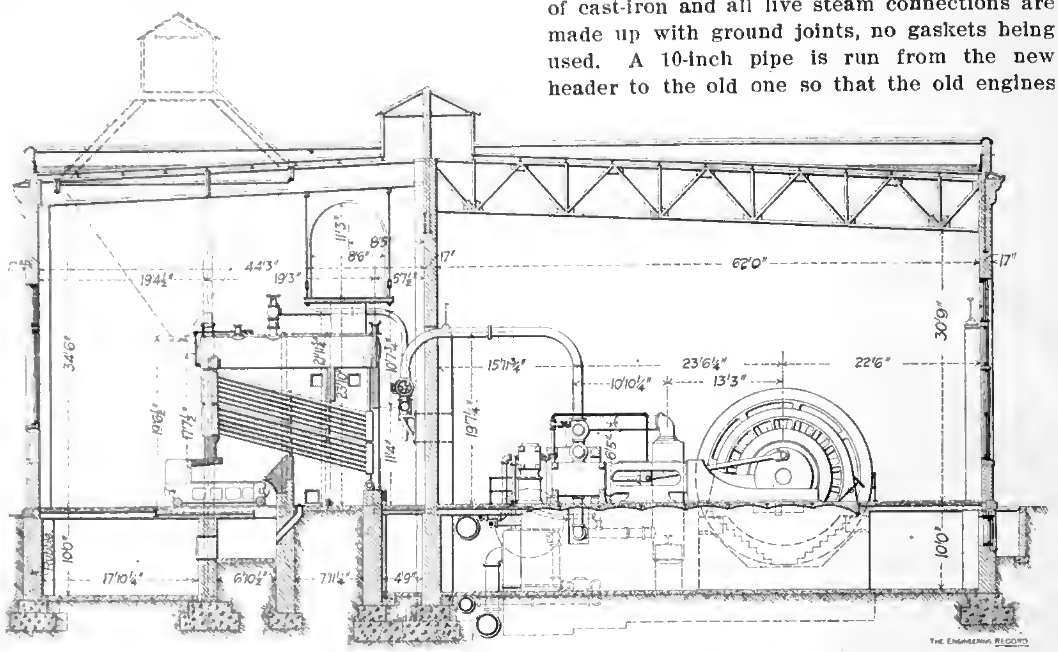
The company recently decided to build some extensive lines out into the country, for which, with the former load, the capacity of the old station was inadequate. The plant was otherwise unsatisfactory, for the boilers were well worn and, although the building was within 200 feet of the river, no condensers had ever been used, conditions which made the fuel charges noticeably high. The company accordingly retained Messrs. Sargent & Lundy of Chicago to design a new plant of thoroughly modern type. After investigation of the conditions in the old station, it was decided to build a new engine and boiler room adjoining the old plant in such a manner that, after the new machinery was put into operation, some of the old apparatus could be removed and the new station extended over the ground occupied by the old plant. The general scheme of this extension is shown in one of the illustrations, the proposed future addition to the new station being shown in broken lines. It was decided to utilize temporarily the old stack which projects out from the old building at a convenient point. The location of the new engine and boiler rooms was determined with due consideration of convenience in receiving coal on a side track from the Chicago & Northwestern Railway and also of the source of condensing water supply from the river.

The boiler room is designed for overhead coal bunkers and a complete system of coal-handling machinery. It was not considered desirable to install these bunkers at the present time, but the roof girders of the boiler room are so built that the bunkers can be readily attached to them at any time. For this purpose also the front ends of the boilers are carried on heavy structural columns which are designed so that they can be extended up to the roof girders, when the bunkers are put in, so as to carry the additional load of the latter. The coal track is outside of the new boiler room and parallel to it, and when the coal bunkers are added the building will be equipped with a conveying system such that the cars will be unloaded into a hopper, and the coal conveyed by machinery to the bunkers, the ashes being carried out from the ash pits in a reverse manner. For the present, however, arrangements are made for unloading the coal cars on to the boiler room floor, from which the stoker hoppers are filled by hand. Under each of the boiler room windows is a cast-iron frame the full width of the window, and this frame is covered by a sheet steel door stiffened with angle irons and provided with counterweights so that it can be swung back against the coal car. These doors have side projections so that when open they form chutes over which the coal is unloaded on to the floor.

The boiler equipment as at present installed in the new station consists of four horizontal water-tube boilers manufactured by the Aultman & Taylor Machine Company, Mansfield, Ohio. They contain 4,400 square feet of heating surface each and are equipped with Aultman & Taylor chain-grate stokers of about 75 square feet of grate surface. As will be seen from the cross-section, the boiler-room is provided with basement ash-pits and with a sheet steel overhead flue. In view of the future development of the station, this flue was made of the same sectional area throughout, the idea being that when the first extension is made to the new station it may possibly be desirable to make it at the end opposite to the old station instead of in the manner indicated in the plan.

At the end of the boiler room against the wall of the old building is located a Stilwell cast-iron heater of 350 cubic feet capacity. This will heat feed water for six boilers such as are now installed, at their maximum capacity. The heater is located on a gallery, with the feed pumps immediately under it, and the piping connections are so made and the gallery so built that when the new station is continued, as shown in the plan, the heater, gallery, pumps and connections can all be moved bodily and set up against the wall of the future stack, so as to make room for another battery of boilers where they now stand.

The steam header in the new boiler room is of cast-iron and all live steam connections are made up with ground joints, no gaskets being used. A 10-inch pipe is run from the new header to the old one so that the old engines can be run from the new boiler plant.

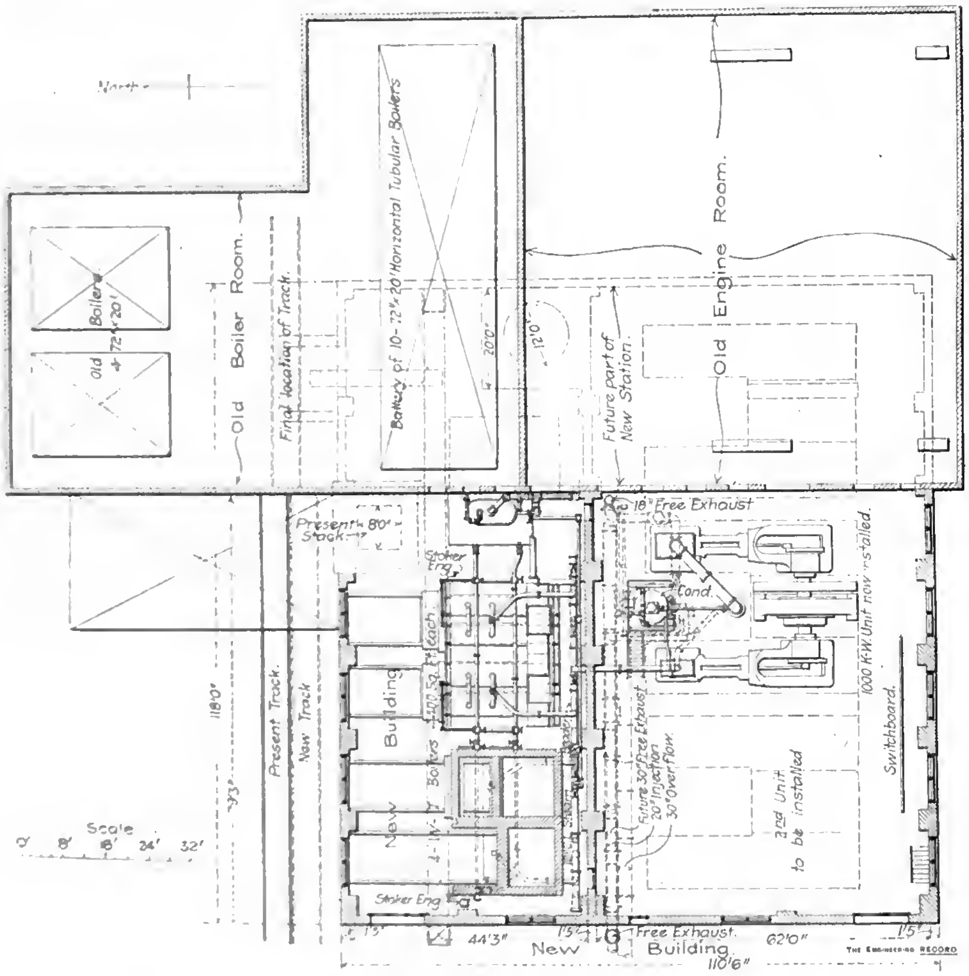


CROSS-SECTION OF NEW POWER PLANT, DES MOINES CITY RY. CO.

The present equipment of the new engine room consists of a 26 and 52x60-inch Allis-Chalmers engine direct-connected to a General Electric 16-pole 1,000-kilowatt 575-volt railway generator making 80 revolutions per minute. This unit is equal to a maximum continuous load of 1,500 kilowatts. It is intended to install another unit of the same size at an early date.

The company runs from 60 to 65 cars, chiefly of the double-truck type, in regular service, and the load at the switchboard varies from 800 to 1,400 kilowatts, with an occasional peak somewhat in excess of the latter amount. The 1,000-kilowatt unit installed will, therefore, carry the load under all ordinary conditions of the traffic.

The company is now building an interurban road to run from Des Moines to Colfax, a distance of about 25 miles through the towns of Mitchellville and Altoona. Electrical apparatus for this extension has recently been ordered from the General Electric Company. A 300-kilowatt inverted rotary converter will be installed in the new engine room, with 330 volts on the alternating-current (three-phase) side. This will be stepped up to 16,000 volts and transmitted to a sub-station at Mitchellville, 19 miles from the power station, where the process will be reversed. The transformers used are the General Electric air blast type, four of 110 kilowatts being put in at each end of the line.



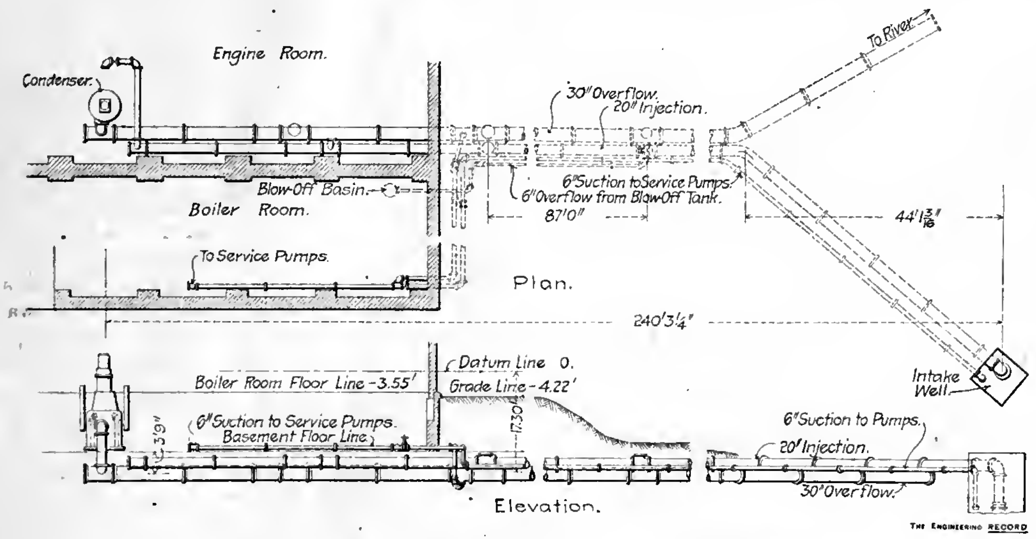
PLAN SHOWING RELATIVE LOCATION OF OLD AND NEW STATIONS.

To revert to the special features of the engine room of the new station, the engine being of course condensing, an independent Allis vertical, flywheel, injection condenser has been installed between the cylinders of the engine. An intake crib is located in the river near the bank and a 20-inch cast-iron injection pipe runs from it to the condenser, and a 30-inch overflow pipe carries the discharge back to the river. These pipes are large enough for four of the 1,000-kilowatt units. Openings are left for future connections so far as possible. The engine room is built for an overhead electric crane although this has not as yet been installed.

An automatic oiling system is installed with reservoir tanks in the basement and overhead distributing tanks into which the oil is pumped from the former. The new type of Lunkenheimer pressure oil cups are used on the engine throughout, and Turner oil filters are installed in the basement to which all the oil drains from the bearings are piped.

The new boiler plant has been in operation for some weeks and the new engine has just been started. The improvement in the fuel economy even since the new boilers were started has been very marked.

The general manager of the Des Moines City Railway Company is Mr. G. B. Hippee, to whose energy the recent improvements are largely due. Mr. J. E. Welch is the master mechanic and has direct charge of the power station. By his continued watchfulness he has been able to run the old plant through many trying load peaks without a mishap. The new station is fulfilling his anticipations of several years past. The new power plant, however, is only one of many interesting features the company can show to visitors. It has a repair shop and small foundry unusually complete for a road of its size, and builds a number of new cars each year as well as makes over the old rolling stock.



GENERAL ARRANGEMENT OF PIPES TO THE RIVER.

Cement Testing in Municipal Laboratories.

A paper, slightly condensed, presented by Mr. R. L. Humphrey before the American Section of the International Association for Testing Materials.

The study of the equipment and methods in use in the various municipal laboratories, particularly so far as they apply to the tests of cement, is exceedingly interesting, and one which presents a wide field for discussion.

The first record of any systematic experiments with Portland cement were made in France by the engineers of the Ponts et Chaussées, by whom this material was employed on a large scale as early as 1850. Their standard of excellence provided that a Portland cement should have a specific weight of 1,200 kilogrammes per cubic meter (103 pounds per imperial bushel), and that briquettes of 1½ inch section, equal to an area of 2¼ inches, should develop the following tensile strengths:

Age.	Neat.	1 cem.; 2 sand.
2 days	140 pounds	...
5 "	280 "	140 pounds
30 "	530 "	280 "

In the latter part of 1858 John Grant began a series of tests in connection with the London main drainage works, and in 1859 we find the following clause in the specifications for this work:

"The whole of the cement to be used in these works is to be Portland cement of the very best quality, ground extremely fine, weighing not less than 110 pounds per striked imperial bushel, and capable of maintaining a breaking weight of 400 pounds on an area, 1½x1½ inches, equal to 2¼ inches, 7 days after being made, in an iron mold, and immersed in water 6 of these days."

Grant maintained no central laboratory but established small laboratories on various parts of the work and equipped them with a few briquette molds, a machine for making tests of tensile strength, and apparatus for ascertaining the weight per bushel. It is interesting to note that Grant subsequently changed the form of the briquette and reduced the section to one inch. He later added a test for fineness. Faija devised a test for constancy of volume, Vicat an apparatus for measuring the rate of setting, while Michaelis and others added improvements in both methods and apparatus. The methods of testing and the specifications proposed by Grant furnished the precedent which is followed by engineers generally in this country and in Europe.

In the half century which has almost elapsed since these tests were proposed, little or no change has been made in the general character of the tests, although the methods and apparatus have been considerably improved, while the quality of the cement produced, particularly Portland cement, has been wonderfully improved.

It seems remarkable that this improvement in the quality should take place without a corresponding improvement in the methods of tests. For as Portland cement came into more general use, we find the engineer, in his anxiety to establish the qualities if this new product, applying a greater variety of tests of increasing severity. The principal qualities sought, viz., fineness, rate of setting, strength and soundness are, however, the same to-day as in the days of John Grant. As a rule the early laboratories were field laboratories, that is, they were located on the work in which the cement was to be used, and the equipment was necessarily limited. Gradually laboratories of a permanent character were established for the purpose of more accurate tests and for investigation.

There are but few thoroughly equipped municipal laboratories in either this country or abroad. The laboratories connected with the technical schools are for the most part fairly well equipped. This is particularly the case abroad. One of the most important of this kind is the laboratory of the Ecole des Ponts et Chaussées. This laboratory was established in 1851 as a chemical laboratory for the examination of limestones, lime, cement, mortars, puzzolanas, and other substances employed in construction. It is interesting to note that, in the circular letter issued about this date, "the engineers of the Ponts et Chaussées and persons who desire tests and analyses made can send their samples to the laboratory which will make the examination gratuitously." This laboratory was established as a permanent laboratory in 1884 for the systematic inspection of lime, cement, mortars, etc., used in construction of public works in France under the direction and charge of the engineers of the Ponts et Chaussées.

The laboratories connected with the technical schools at Munich and Charlottenburg in Germany, the laboratories at Zurich, Switzerland, and at St. Petersburg, Russia, are exceedingly well equipped and are making many valuable and important investigations. That at Charlottenburg is a particularly elaborate affair, being provided with separate rooms for the individual investigators.

In 1877 the Association of German Cement Manufacturers was formed. This association has by its efforts accomplished more towards the unification of methods of testing and the improvement of the quality of cement than any other society, and their standard rules adopted throughout Germany have been closely followed by the engineering profession generally.

In this country among the very earliest municipal laboratories was that established under the Engineer Commissioner of the District of Columbia by the first Board of Commissioners in 1878 and under the charge of Mr. E. J. DeSmedt. Its original purpose was for the use of Mr. DeSmedt in laying the first asphalt pavement in Washington. Mr. DeSmedt was succeeded by Mr. Clifford Richardson in 1887.

The Department of Docks of the City of New York established a laboratory for testing the cement in 1870. Three years later Capt. W. W. Maclay assumed charge of it. Many of the earlier contributions to cement literature were the result of the investigations made in this laboratory. Captain Maclay also devised the Maclay hot bath tests which were so generally adopted in this country. The Boston Main Drainage Board in 1878 established a cement laboratory under the direction of Mr. Elliott C. Clark.

Under the Metropolitan Sewerage Commissioners of Massachusetts an elaborate and well equipped laboratory was established at their principal office in Boston in 1890 at considerable expense; this laboratory was unfortunately destroyed by fire in 1893 and since this time the Commissioners have expended no large sums on a permanent laboratory. They have, however, equipped several field laboratories at convenient points along the work.

The laboratory of the St. Louis Water Works Extension was established about 1888 and for a number of years was in charge of Mr. S. Bent Russell. In 1895 the laboratory was removed to a point further down town and the Sewer and Street Departments joined with the Water Department in operating it for testing cement, paving brick and other materials.

The City of Baltimore's laboratory for testing cement was established about 1891 under the direction of Mr. C. B. Marriott. The equipment of this laboratory was meager and the methods crude, and have been succeeded by the laboratory established in 1900 under the direction of the Highway Division of the State Geological Survey. The latter is equipped principally with apparatus for testing the materials used in road construction, the equipment for cement tests being of a rather limited character.

The laboratory of the City of Chicago was established in 1894, with Mr. S. M. Rowe in charge. The equipment of the laboratory is fairly complete and consists of a Fairbanks testing machine, a 20,000-pound Riehle tension and compression machine, storage tanks with a capacity for 7,000 briquettes, together with the necessary molds, set wires, scales, etc.

New York has from time to time maintained laboratories for testing cement under the direction of the various departments. The equipment of these laboratories was limited and more or less crude, was adapted for field work only, and therefore met with indifferent success.

In 1899 a laboratory was fitted up by the Commissioners of Accounts for the purpose of testing all the material used by the City of New York. The laboratory is under the direction of Mr. Otto H. Klein, chief engineer, with Prof. S. F. Peckham, chemist in charge. The equipment, while on a small scale owing to the limited space set aside for the purpose, is good and sufficient for making all the usual tests, except the compressive and transverse.

Prior to 1892 the inspection and testing of cement in the City of Philadelphia was done in field laboratories and usually on important work only. In that year there was started, in an obscure corner of the city hall, in a very modest way a permanent laboratory for the testing of cements. The equipment consisted of a Fairbanks testing machine, a set of Gilmore wires, an eight-gang briquette mold and a few pans for preserving the briquettes. The work was necessarily of a limited character, was performed in a systematic manner and the results were carefully compiled. Gradually additional apparatus was added, better facilities provided and the scope of the work enlarged. The result of this rather unpromising beginning is a permanent laboratory, with facilities and equipment for making all the tests in general use, whose equal does not exist in the country or which is excelled by but few laboratories abroad. As the engineer in charge I had the pleasure of supervising its development from its inception. This laboratory has done a very great deal towards raising the uniformity and standard of quality of the American cements. The improvements in the quality of the cements furnished the city and the reduction in the cost, incident to the competition which the methods in vogue in the laboratory made possible, have more than compensated the city for its cost of installation and maintenance. The cost of maintenance does not exceed 10 per cent. of the probable annual saving to the city.

This covers in a brief general way the history of the principal municipal laboratories in this country. Laboratories are also maintained by the cities of Cleveland, Indianapolis, Buffalo, New Orleans and others, but they are for the most part on a smaller scale and possess no unusual features. The number of municipalities which maintained laboratories of this character is constantly increasing, although it is to be regretted that neither in facilities, equipment or method do they attain the necessary and desired standard of efficiency.

Municipal laboratories can be divided into two general classes: (1) Field laboratories or those located on the work in which the cement is to be used. Such laboratories are equipped for making only a few simple tests and the work is not carried on in a systematic manner. (2) Permanent laboratories, usually well equipped with apparatus for the thorough investigation of the properties of the materials of construction. Work in the laboratories of this class is carried on in a thoroughly systematic way and the results are carefully compiled and made available for general use.

Aside from private laboratories, more or less well equipped, which do commercial testing, there is a class connected with the technical schools. The latter are for the most part well equipped and many of them make a practice of doing commercial testing and in a few cases have charge of the inspection of the materials used by neighboring cities and towns, while some few others extend the use of their laboratories to the city engineers and county commissioners of the entire State in which they are located. Lehigh University is an example of this class. The work of testing in these laboratories is usually entrusted to the instructors and in many cases the students themselves. As there is a lack of the requisite experience and skill, the results obtained, under these conditions, are of doubtful value.

While the system under which all cements are tested far from fills the requirements, owing largely to the great influence of the personal equation of the persons who make the tests on the results obtained, yet it is nevertheless true that the tests and inspection to which cement are subjected has done more towards improving the quality of cement than any other agency. The manufacturer in order that his product may fulfill the requirements has exerted greater care in the preparation of his output and with a corresponding increase in its quality, both as regards its strength and uniformity. The advent of the rotary kiln has proved another potent factor in the improvement of the quality of Portland cement, indeed the present high standard of quality is due largely to this process. Without the application of systematic inspection by the engineer or consumer, the manufacturer, having no requirements to meet, would fall into careless habits and the standard of quality of the product would gradually fall. When John Grant first proposed a tensile strength of 400 pounds on 1½-inch section at end of 7 days the English manufacturers exerted considerable pressure to have the requirement reduced to 300 pounds fearing they would experience great difficulty in meeting it. That this fear was groundless is shown by the fact that within very short time afterward the requirement was raised to 550 pounds. From the compiled results of tests we learn what tests cement may be reasonably expected to develop. We further learn that those cements which yield the best results in actual use readily meet certain specified requirements. It is therefore natural for the engineer to fix a standard of excellence (based on the results which he has obtained) by which to gauge the acceptability of each shipment. So long as the engineer fixes the requirements of his specifications in this manner, there is small likelihood of a serious disagreement between the engineer and the manufacturer, as to whether the cement does or does not meet the requirements.

It is the class of consumers, however, who draft their specifications with the aid of a pair of shears, that occasion the greatest trouble, not only to themselves but also to the manufacturers. Such persons, as a rule, with their limited knowledge of the properties of cement, select for their specifications the most rigid clauses from a number of other specifications, and the result is a new and impracticable standard calling for impossible and often contradictory conditions. The manufacturer, unless he has a previous knowledge of the personal equation of the person in charge of the laboratory, is loathe therefore to submit his product and chance the possible rejection of a good material required to meet these impossible conditions. It is not surprising that under such conditions the manufacturer refuses to supply cement. As a result the consumer is placed in the embarrassing position of being obliged either to disregard his specifications or change the requirements.

A uniform or standard specification is unquestionably very desirable, but the realization of such a standard is only possible through the adoption of such methods of testing as will secure uniform and comparable results by different persons. A Board of Engineers have prepared a set of specifications for the guidance of the Corps of Engineers of the U. S. A., but it should be noted that they have prefaced these specifications with a detailed description of the methods to be used. It would seem, therefore, that the first step towards securing uniform specifications is the adoption of methods for making uniform and comparable tests. When this has been successfully accomplished standard specifications will not only be possible but will also be the natural sequence.

The testing of cement is an art requiring a combination of skill and experience, and a natural inclination towards scientific research on the part of the person making the test. The wretchedly poor salaries generally paid those in charge and the correspondingly inadequate assistants which such salaries secure, is one of the deplorable features of the municipal laboratories of to-day, the exception being perhaps a few of the larger laboratories where the assistant in charge is content to accept the poor pay for the sake of the reputation and experience to be acquired.

As a rule the assistants in charge have little interest in their work and frequently resign their positions after a few years' service just when they have become experienced and skilful and therefore valuable. The work accomplished under such conditions is inefficient and unsatisfactory. As a result the great bulk of the tests turned out by municipal laboratories, through lack of uniformity in methods and skill on the part of those making the tests, are of little value. It is little wonder, therefore, that there should be such wide difference in the requirements of the specifications of these laboratories. You will find that the specifications issued by laboratories properly equipped and in charge of skilled persons agree much more closely. Municipalities can well afford to maintain thoroughly equipped testing laboratories, conducted systematically and in charge of technically trained engineers, whose compensation will be sufficient to retain their services for a number of years after they have acquired the requisite skill and experience which make them competent and valuable. The wisdom of such an expenditure of time and money will become apparent when the improved quality of the materials furnished at a reduction in cost and the increased durability of the work are taken into consideration.

The number of regular tests to be made in such a laboratory should be few and the methods used the most simple. Ordinarily the tests for determination of strength, neat and with standard sand for seven and twenty-eight days, the degree of fineness, the rate of setting and some simple efficient test for constancy of volume should be sufficient. If the laboratory possess the services of a skilled chemist, chemical analyses should also be made. For further information concerning methods and apparatus to be used in making such tests those interested are referred to the "Journal" of the Franklin Institute for December, 1901, and January and February, 1902.

Another condition, resulting largely from the maintenance of municipal laboratories, particularly those conducted on broad lines, is the better esprit du corps which now exists between the engineer and the manufacturer. The old situation where these parties held aloof and viewed each other with suspicion and often contempt was an intolerable one, and I am glad to say is rapidly disappearing. The advent of the technically trained assistant at the factory and in the laboratory of the consumer has done much to bring about this condition. Instead of working at cross purposes, both parties are bringing their combined knowledge and skill to bear on the perplexing and difficult problems which confront the producer and consumer alike, and are coming more closely together in an endeavor to effect a solution.

At the present time only a few of the better equipped municipal laboratories compile and publish in a systematic manner the results of their tests. These tests serve as a guide to aid the engineer, the architect or the builder who possess no facilities for making tests of this character in selecting the best and most suitable material for their work.

As these results are made under different conditions they are therefore not related, and there seems to be no basis for a comparison. Without a knowledge of the methods in vogue it is impossible to form any idea of the relative quality of two cements where one is tested in one laboratory and the other in another. There is therefore a most urgent need for a central or reference laboratory, conducted under impartial conditions, at the service of the general public, where fixed standards can be maintained and to which all materials of construction can be referred in cases of dispute between the producer and consumer or, for the purposes of general information as to its properties. Several foreign laboratories, notably that at Charlottenburg, Germany, are conducted on these lines, under Government direction and are of immeasurable value. There is no Government laboratory of this character in this country at the present time. Most manufacturers and many engineers will no doubt agree that there is a growing need for the same. Such a laboratory could establish standards of excellence and could conduct its tests in such a manner that the published results would be related and be of general use. The compensation of the assistants in charge should be sufficient to secure and retain the services of competent persons of great skill and broad experience.

Neither municipal or private laboratories as a rule have the time requisite for carrying on research work of any magnitude. A government laboratory aside from its use as a standard reference laboratory could very properly conduct investigations with a view of solving some of the very perplexing problems connected with the production and use of cement.

We are now entering on a new era, an era which has been appropriately called the "age of cement." The varied applications of cement in constructive work, especially the rapidly increasing use of steel-concrete, render a better knowledge of the strength and properties of the principal material used highly essential. The accurate determination of the properties of this material are more difficult than is the case with any other material of construction. It is of vital importance that this material should not only harden rapidly and attain great strength, but what is far more essential, that it should maintain this strength. A knowledge of the quality and properties of cement becomes, therefore, a matter of the greatest importance and demands that the testing should be conducted in laboratories possessing the best possible equipment, using the best methods available and under the supervision of skilled technically trained assistants.

Retrimming Coal in Bunkers is provided for in the Bristol, Eng., central power station by the use of 12-inch steel pipes, which drop from the bunkers through the boiler room into the basement. Through jaw valves the coal is delivered to the conveyor and elevated for the desired distribution in the bunkers.

The Brooklyn-Manhattan Rapid Transit Railroad.

On July 21 the Board of Rapid Transit Railroad Commissioners of the city of New York will open tenders for the Brooklyn-Manhattan underground railroad, an undertaking which presents several features of the gravest engineering difficulty. Nowhere on the line of the railroad now under construction for the Commission are the conditions of the excavating or tunneling comparable in difficulty with those along certain portions of this new road, which, in places, must pass through a narrow, crowded street close to the foundations of some of the loftiest buildings in the world. Another section which will present unusual conditions for the contractor to overcome is the tunnel under the East River.

The new road begins under the southern terminus of the road now under construction, near Park Row and Broadway, and will have two tracks running down Broadway, Bowling Green, Battery Place, State Street and Battery Park to a loop under Battery Park and Whitehall Street. There will be five stations along this route and just south of that at Bowling Green there will be the branching point of the two tracks running to Brooklyn. These tracks will pass under the lines running to South Ferry, so as to avoid grade crossings. The Brooklyn tracks will be under Battery Park, State Street, Whitehall Street, South Street, the East River, Furman Street, Joralemon Street, Fulton Street and Flatbush Avenue to the Long Island Railroad station.

The contract requirements for the construction in Manhattan are drawn with minute attention to keeping the streets as clear as possible for traffic and particularly for the fire department. This part of the route lies through the most important business center in the country, and there is also a section of the route along Fulton Street in Brooklyn which is almost as important. Here the contractor must work at least two eight-hour shifts each day, and between 8 A. M. and 6 P. M. Broadway must be maintained in a condition for ordinary travel unless the chief engineer gives special permission for relaxing this requirement at some point. On both the Brooklyn and Manhattan shores the route lies under piers, and here the contractor is required to carry on his work so as to afford free access to the docks and wharves at all times. The subaqueous portions of the road will be driven by shields and compressed air; the other portions by such methods as seem most suitable for the several localities.

The general features of the construction do not differ materially from those on the road in Manhattan now approaching completion. Some of the special requirements looking to the comfort of the public during construction are more immediately interesting. For example, the needs of fire protecton are thus guarded:

"Wherever work is being carried on by open excavation, free access must be given to every fire hydrant and fire alarm box, and, when required, hydrants shall be extended by suitable tube or piping to an accessible point as approved by the engineer. At all times and in all places no materials must be piled within 10 feet of any fire hydrant or fire alarm box; and where materials are piled near to a fire hydrant or fire alarm box, and to such height as to obstruct a sight of the same, the position of such hydrant or fire alarm box shall be indicated by suitable signals, both day and night. All work in excavation must be so conducted or bridged if necessary as to give the fire department access at all times and in all places to any building or buildings for the extinguishing of a fire."

Readers of Mr. Charles Sooysmith's paper on foundation work in lower New York, presented a few years ago before the American Society of Civil Engineers, will recall his statements concerning the occasional unusual difficulties in constructing the foundations of lofty buildings in the neighborhood of the lower end of Broadway. The clause in the contract specifications governing work in these localities is as follows: "In the event of encountering quicksand, subsurface streams or similar dangerous contingencies, or where passing especially heavy buildings which by their construction or position might bring a great pressure on the trenches, the right is reserved by the Board for the engineer to direct that such buildings shall be underpinned or that special sheeting shall be driven in such manner and to such depth as the engineer shall direct, or that but a short length of trench shall be opened at one time, and furthermore to direct, if necessary, that the same shall be securely sheeted and braced on all sides after the manner of a shaft, and that the permanent work be constructed in such shaft and backfilled before another opening is made. Whenever water is encountered in trenches, the same shall be removed by baling or pumping, great care being taken when pumping that the surrounding particles of soil be not disturbed or removed. If necessary to prevent such disturbance, the pumping must be done by a series of driven wells whose points are protected by fine wire cloths and the rate of flow at each well being made so slow as not to remove the particles of soil; or the pumping must be done by other means approved by the engineer. The delivery from all pumps shall be conducted into the adjacent sewers and the delivery pipes shall be so arranged as to be readily inspected at all times to ascertain if the water is free from particles of soil."

Peat Fuel is manufactured by the aid of electricity at Stangfiorden, Norway. The wet peat is brought to the factory direct from the bog by water, in lighters of about 100 tons capacity. The boats are discharged by mechanical power and the peat is dried and pressed in a 5-horsepower press which can turn out 2,500 pressed blocks of peat per hour, each measuring 31.5x3.15x3.15 inches. The average weight of dried peat in each block is 4.4 pounds. The briquettes are then dried on wagons in drying tunnels, 140 briquettes per wagon on 10 shelves. The air draft through the tunnels is set up by fans electrically operated and is heated by the waste gases from the retorts. The air has a temperature of 194 to 212 degrees Fahrenheit at the top end of the tunnel where the wagons emerge and of 104 to 122 degrees at the lower end when they enter. From the tunnels the briquettes are carried to the retorts which are upright cylindrical vessels of iron, about 6.56 feet in height and 3.28 feet in diameter. The retorts are provided with spiral resistance coils and the blocks of peat are built up in actual contact with these, until the retort is entirely filled with a pigeonholed mass of peat, in the center of which the heating agent lies. Losses by radiation are minimized by lining the retorts with asbestos. The gaseous products pass away by openings in the retort cover, and after scrubbing are employed for heating the air used in the drying tunnels. The tarry liquid condensed in the gas pipes and in the scrubbers contains tar oils, ammonia and other compounds. The peat fuel remaining in the retort is allowed to cool down to 235 degrees Fahrenheit before being discharged. According to "The Engineer" the average yield of air dried peat is as follows: peat fuel, 33 per cent.; peat tar, 4 per cent.; tar water, 40 per cent.; gaseous products, 23 per cent.

The Financial Questions in Water-Works Valuations.

Abstract of a paper read before the American Water-Works Association by John W. Alvord.

The large number of water-works plants originally built in this country by private capital is lessening in number year by year, as the desire for municipal ownership stimulates cities to acquire such plants, either through the purchase provisions in the original franchises, or through special negotiations, or by reason of the expiration of the franchise itself. This general movement on the part of the American cities to acquire municipally operated plants has given rise to very many interesting financial questions as to the proper and just returns to be made to the original investor or owner of such securities.

It often happens that water-works men and hydraulic engineers, skilled in the construction and designing of water plants, are selected as arbitrators under some special clause of the franchise, or are requested to present the claims of one or the other of the interested parties. Such men are unquestionably well qualified to judge of the physical value and depreciation of the plant which it is desired to purchase, but it is observable that not every engineer or water-works man charged with such responsibilities, has clear and distinct notions of the financial questions involved.

The usual method is for an arbitration board to meet and after careful inspection of the plant to proceed to estimate its cost in detail, at the prices for materials and labor prevailing at the time of such appraisal. This being accomplished, the depreciation is then estimated. Here the skilled water-works man or hydraulic engineer is at great advantage; they are the men best fitted to know intimately from practical experience the life of the various parts of the plant under varying conditions. But from this point on, the arbitration board faces problems which necessarily fall under the head of financial, rather than engineering. The main questions of this kind which invariably arise are three in number and may be described as follows:

First: What is the business value of the plant, built up as it has been by the energy, perseverance and solicitation of the officers in charge, as distinct from the inert plant itself, without customers or connections? This feature of value has been aptly termed by the Judge in the Kansas City case where its distinguishing characteristics were pointed out as the "going value."

Second: What is the value of the franchise, if any, and how shall it be computed?

A third class of financial problems is often encountered which more commonly occurs in court cases; this is the problem of adequate return upon the property in the form of hydrant rental or rates to consumers. This class of problems has been and will be specifically encountered under a recent decision of the United States Supreme Court in the Rogers Park case, where it is determined that cities have the right to regulate water rates, even though fixed apparently by contract in the franchise, provided a fair return upon the capital invested is allowed.

The Business Value.—The element of "going value" has been before described as the element of growth in the plant irrespective of its physical condition. It is comparable somewhat to that indefinable quantity known in other lines of business as "Good Will." Nevertheless it is something more than good will in water-works business, as it represents what might be more aptly described as "connected good will," that is to say, the acquisition of customers who have invested considerable sums in actually connecting their premises with the plant of the company, and provided appliances for the use of the water which it can deliver. In the case of the National Water-Works Company, of New York, vs. Kansas City, in the Circuit Court of the United States for the Western District of Missouri (Fed. Rep. 62-853), the question of the value which attaches to the water-works plant because of its being a "going concern" in use and earning, was brought to a clear cut issue, and it was decided that such value was properly a part of the plant which should be added to the cost of reproduction. This decision has been now well nigh universally accepted by water-works arbitrators as well settled, and is applied whenever this consideration is not specifically excluded by the terms of the franchise or agreements between the parties in interest.

It is not intended here to discuss the merits or demerits of this decision in that particular case or its justice in general application, but rather to point out a method for rationally applying it to actual conditions. It is the writer's belief that the best and most rational method of determining the going value of an ordinary plant was first pointed out by Mr. Benezette Williams, one of the arbitrators in the purchase of the Dubuque water-works by the city. Briefly described the method was as follows:

It is assumed that a new plant will be constructed, the inception of which is coincident with the date of arbitration. Such new plant is to be of an equal capacity with the older plant under consideration, and a due allowance of time in which to construct this new plant, and the necessary capital to be invested in it from time to time is estimated. At the completion of this new imaginary plant, it is assumed that it commences to obtain business in that community from those who are not previously accustomed to the free use of public water, except in a general way; that it is to acquire the business ability and consequent increase in number of customers which the earlier and older plant went through within the early years of its existence. An assumption of the amount of business thus created for each year for a period of years in advance is carefully computed and estimated by the board of arbitrators. The losses of interest upon capital invested are duly fixed, as well as the first absence and later addition of revenue from hydrant rentals, and a table is prepared showing each year, the total business developed and the total losses if any. After this is completed a forecast is made of the business of the older works for the same period of time in the future that it takes the business of the new works to equal the business of the old works. If the business of the old works is found to be a growing one it will be a longer period that the new works will require to overtake it than will be the case if the business of the older works is stationary or decreasing. In general, the differences which might be called the debits and credits of this new imaginary plant and the debits and credits of the older working plant are reduced to their present worth at the time of appraisement, and an estimate is made up which will adequately represent the financial advantage which the old works (already fully equipped and in running order and having a large number of profitable customers) will have over the new works, where everything must be built and customers secured.

It is necessary in making this suppositious estimate of the new plant to consider it in no way a competitor of the older works; there is not supposed to be competition between the new and the old, but it is left to the experience of the board of arbitration to consider how long it would take a new company to build new works, and build up business for the new works until they have overtaken the business of the old company should it continue to occupy the same territory. It is observable, of course, at once, that such a method requires experience in financial matters, as well as experience covering the financial management of a large number of water-works plants.

The writer has applied this method in a considerable number of cases of a varying nature, and has observed its application in other cases outside of his experience, and believes that it is coming to be understood as being the rational way of determining this perplexing question to the satisfaction of the expert who may be called in, and the more wide the experience of the expert the more just will be the application of the method as a rule.

The Franchise Value.—The second item which is to be considered in fixing the value of the water plant is the question of the value of the franchise, if any. This is an exceedingly difficult financial question, and is first of all often excluded from the consideration by the terms of the franchise itself. Of course, it is not a consideration in cases where the franchise has expired. But where negotiations are under way for amicable adjustment irrespective of the opportunity of purchase offered by the terms of the franchise itself, or where it is not excluded from consideration by the terms of the franchise, it becomes a problem of some difficulty. There are two methods by which it may be estimated. First: The physical value of the plant and its depreciation and going value may be entirely neglected and the entire valuation of the plant fixed upon the basis of its earning power throughout the remaining life of the franchise, and its probable value for sale or franchise renewal at the same time. It is evident that it cannot be considered as a revenue producer for all time to come, but the time in which it may earn revenue being limited, the probable net revenue for each remaining year of the franchise life must be estimated and capitalized at a sum which if put at interest would pay such yearly revenue and extinguish itself at the end of the franchise period. To this must be added the value of the plant as physical property at the end of the franchise period giving due consideration to what it may be worth at that time to the city as possible purchaser or parties obtaining a renewal of the franchise, or the cost to the original company for the renewal of its franchise.

The question of the element of value in the physical plant at the termination of the franchise is also a difficult one. In many instances radical changes in the water supply are expected by the citizens. Purification works may be demanded, or expensive alterations may be insisted upon which will have a great bearing upon the element of value of the plant to the city.

A second method of determining franchise values, if any, is to proceed first to estimate the physical value of the plant as shown by its cost of reproduction, less its depreciation. Secondly, to compute the going value. Thirdly, to determine whether the net revenue is paying interest on a capitalized value greater than that indicated by the sum of the physical value and the business value added together. If such capitalized value is less than the sum of the physical and business value, then there is evidently no additional value to the franchise as such, but if the income of the plant capitalized is found to be greater than the sum of the physical and business value, it is evident that in the majority of cases there is to be added a third element of value, created by the amount which the franchise itself is worth over and above any other values which may have been estimated. To determine the present worth of such an added franchise value, the excess income over and above that necessary to cancel all other obligations (including the payment of interest upon the sum of the physical and business values), should be estimated throughout the remaining years of the franchise, and the several sums should be carefully reduced to their present worth and added in as a portion of the final value of the plant.

Now, all this seems somewhat complicated, and indeed is complicated not only in the abstract, but by local considerations, and by the language in the individual franchise. But the writer is convinced from such experience as he has had that the above outline furnishes a rational and just method of determining such values, and is capable of being carefully studied and worked out in each case indicated.

The Fair Return.—The third class of financial questions often arises in connection with what is known as hydrant rental. It is sometimes the case that the franchise is quite silent upon the allowance to be made for additional hydrants, after fixing the amount to be paid for the first installation. Often the franchise states that the value of the additional hydrants will be fixed at a *fair rate*, though not specifying by what manner or means such rate shall be determined. A great many efforts have been made to show what the average hydrant rental is in different communities, or in different States, or in the country at large, but about all the satisfaction that can be derived from such tables is the opportunity to observe that there is a wide variance in the amounts paid for hydrant rental at different places and under different circumstances.

One view of this problem is that hydrant rental, although apparently a specific payment for a specific service, is in reality a bonus given by the city to the water company as an inducement for it to locate, operate and maintain its works, it being found that private capital cannot afford ordinarily to establish works and operate them for the revenue derived from domestic consumption alone. When this is fully understood, it will be perceived that consideration of the hydrant rental question is indeed but a consideration of the more important question as to what may constitute a fair return to the water company upon its capital invested.

Another view of the hydrant rental problem is that it is a specific payment for a specific service, viz., for means of extinguishing fires, and as such it should be made proportional to the service rendered. This view, it can be shown, will lead either to an absurdity or to the precise method of considering hydrant rental as a bonus. For if fire service is to be paid for in proportion to the service rendered, millions of dollars must be used to measure the possible losses due to the absence of suitable mains and fire hydrants in a city of even the ordinary size where the actual investment for fire prevention may be measured in thousands of dollars. A few moments reflection will convince any one that such a measure of value for fire hydrants is out of the question.

But it is often assumed that the measure of value of fire hydrant rental is the investment necessary to provide mains of a suitable size, and pumping machinery of sufficient capacity, and other appurtenances sufficient to provide fire protection rather than domestic consumption. If it is attempted to carry this theory into practice, we must estimate the cost of two separate works: one proportioned for domestic service only, and the other proportioned both for domestic consumption and fire service, the difference between the two representing the cost of increased capacity necessary for fire service. But fire service cost not only depends upon differences in first cost, but operating expenses, interest, sinking fund, and all other fixed charges as well. Therefore it is necessary to know the "*fair return*" upon each of these hypothetical works as well, in order to arrive at the true investment for fire protection alone.

Therefore, it will be seen that to consider hydrant rental as anything else than a portion of *fair return* is to involve oneself in a complicated problem where a simple problem will answer better.

It is indeed too often true that hydrant rental is not fixed with the consideration in mind that it is only a portion of the fair return, but it does not vitiate the final conclusion that this is the real problem at issue. It has been the writer's fortune to study this question in several recent important cases where it was in issue, and so far as he has observed the problem, it is clearly not a question of the remuneration to the company for special services but a question of the fair return to the company upon its invested capital after considering it in the possession of certain private revenues and privileges which assist in rewarding that capital to a limited extent.

This broad method of treating this question eliminates many difficulties which have heretofore surrounded the question of hydrant rental.

Another class of questions involving the fair return is brought up by the recent decision of the Supreme Court in the Rogers Park case before mentioned. If we assume, as it would seem from this decision that we must, that a franchise for water supply is not a contract in so far as the fixed rates therein mentioned are concerned, and that city councils have the right from time to time to readjust such rates, as they may see fit, providing always that in determining on such revised rates, a fair return be made upon the capital invested in such plants, the question as to what is a fair return becomes an exceedingly interesting and important one, not only to the investor, but to the municipality, its citizens, and the courts as well.

What then is the fair return for capital invested in a water-works franchise, and how shall it be determined?

It is evident that municipal plants do not furnish sufficient data for us to determine this question, for municipal works as a rule do not consider interest on original investment unless represented by outstanding bonds. Municipal works provide no sinking fund such as has been described in this paper, nor do they pay taxes. As a rule, improvements in well established municipal works are often paid out of revenue and do not show an increased capital expenditure. Discarded machinery or other appliances in municipal works is never written off as depreciation, but the total cost or investment, if ever known at all, is known as a constantly increasing sum which represents all classes of investment and renewal. Municipal works are therefore quite useless as a guide to the fair return on capital invested.

In the author's opinion the fair return will be found under natural conditions to consist of the following items:

1st. Interest on capital invested.

(a) On bonds and their discount or renewal.

(b) On cash advanced by the promoters.

2d. Proper and reasonable operating expenses including fair salaries for good business management.

3d. Maintenance and renewals to make good not only actual depreciation but necessary alterations.

4th. Taxation, if any.

5th. A sinking fund to make good possible loss in value of plant at end of franchise period due to forced sale or altered requirements which decrease value of some portion of plant.

6th. A reasonable profit.

The method of procedure believed by the writer to be the best for the purpose of deriving the above items of fair return is to take into consideration the whole investment and revenue producing power of the plant, and to determine its future revenue by comparison with its past history. After estimating the physical value of the plant less its depreciation and adding its business value, it should be determined if the franchise has any value by the method discussed under the second head of this paper, and if it has, the final value of the plant may be summed up from these three items. Upon this final value as a basis should be determined in percentages the items of the fair return.

Interest upon capital invested in water-works franchises generally commands a high rate due to the shortness of the term of franchise, and often to the possibility that before the term is over altered conditions of supply may vitiate the value of the works. A new source of supply may be demanded, or purification works may be desired, thus compelling before many years the investment of new capital and the obliteration of a large portion of the original values. The sentiment for municipal ownership now common all over the country, prompts many communities thoughtlessly to try to depreciate the value of works in the hopes of securing them at advantageous rates, thereby engendering much bitter feeling on both sides to the controversy, and often succeeding in seriously depreciating the value of the security.

Interest on bonds should include cost of selling them and renewing them when necessary.

A large amount of practical experience is necessary to determine what are fair and reasonable operating expenses. Oftentimes plants are wastefully and carelessly managed and the operating expenses are abnormally high. At times lack of suitable investment in economical appliances prevents economical operation. In some franchise plants salaries of the higher officers are abnormally high; in others they are abnormally low, due to the officers being stockholders, etc. Operating expense account in many plants often erroneously contains charges properly belonging elsewhere, such as maintenance, renewals, or even new investment.

Maintenance and renewal should be an amount which will keep the plant not only in good repair but in such condition that it may be economically operated. Maintenance should make good depreciation, but should not cover additions to the works such as would fall under the designation of "New Capital Invested." The line here is a hard one to draw in many cases, as for instance where a new main of large size replaces an old main of smaller size.

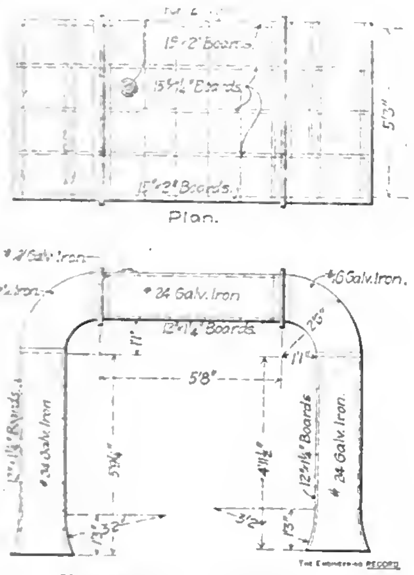
Taxes are generally made against waterworks after certain dates specified in the franchise.

The sinking fund should be such that it will make good all element of uncertainty. If the entire plant is certain to be sold to the city at the end of the franchise period, so that its cost is made good to the original investor, no sinking fund is necessary. But if the city may desire to secure the distribution system only, and will wish perhaps to locate a new pumping station, or develop a new source of supply, then the sinking fund should be calculated in a sufficient amount to make good the loss to the company upon the pumping station. Or, take another case where there is no probability of change in the system, or desire for a new or different water supply, but where difficulties may be encountered in renewing the franchise, then the sinking fund should be so calculated as to cover all possible loss to the original investors produced by negotiations for new franchises, or for the necessity of selling to the city under pressure at the termination of the franchise.

An element in the fair value of any plant is the return to the investor not only of interest upon that portion of actual cash which he has put into the plant, but a reasonable profit upon his money. Were water-works franchises perpetual a reasonable profit might be a comparatively small one, and the interest to the investor might be comparatively low, but with water-works investments in this country terminated as a rule at periods of 25 to 30 years, a higher rate of interest to the investor must of necessity be expected, than would be the case with a higher class security. This last element of fair value is of course the most difficult one to determine, but with considerable experience in the financing of new enterprises, a water-works expert may, in any individual case, arrive at what seems to him to be a fair return under the local circumstances, together with the outlook as it may be at the time of appraisement.

Experiments on the Clarification of the St. Louis Water Supply.

Experiments with the water supply of St. Louis to determine the comparative merits of clarifying the water by passing it through settling tanks connected in series and in parallel have been begun by Mr. Edward Flad, water commissioner of that city, at Chain of Rocks. Heretofore the clarification has been performed entirely by tanks connected in parallel. Now, however, one-half of the water from the low



Experimental Syphon.

service pumps will flow continuously into one end of basin No. 1, through some large syphons at the other end into basin No. 2, and then through syphons at the opposite end from the inlet into basin No. 3, from which the clarified water will flow into the drawing conduit. The other half of the water pumped will flow continuously and equally into basins 4, 5, and 6, and over weirs on the opposite side into the drawing conduit.

During the tests the inflowing and outflowing water will be sampled occasionally and the turbidity measured by the U. S. Geological Survey turbidity rod of 1902, described in The Engineering Record of June 14. The suspended solids will also be determined, thus giving data as to the comparative merits of using the basins in parallel and in series.

The syphons, being for experimental purposes only, are of wood framing covered with galvanized iron. The iron flanges connecting the lengths of galvanized iron are riveted onto the latter and bolted together with ⅝x1¾-inch bolts, the joint being made air tight by using a rubber gasket. Three syphons are used over each wall, and there are four compartments 1 foot 3 inches square in each syphon, making something over 18 square feet total area of cross section of the three syphons. The height to which the water is to be raised is from 3 to 4 feet. The intake ends of the syphons are 4 feet below the water surface, and both ends are flared. The first series of syphons has a summit 5 feet 8 inches long, and the second 37½ feet. A hand vacuum pump can be used to prime the short ones, while a similar pump operated by a 1 horse-power electric motor is used to prime the others, this operation taking about 20 minutes. If the results of these experiments warrant it, it is expected that a permanent system of cast iron syphons may be installed and the entire six basins operated in series.

Sewage Disposal Works at Bury, England.

A rather unusual combination of sewage purification methods is chemical precipitation followed by bacterial treatment in contact beds. This is the system adopted at Bury, England, as described in an article in "The Surveyor" some time ago, from which the following account was prepared:

Upon entering the works the sewage is received into an inlet chamber controlled by shuttles, so as to regulate the quantity of sewage to be treated. It then passes through the detritus tanks, where the heavier matters contained in the sewage are deposited, while the lighter floating matters, such as rags, paper, corks, etc., are intercepted by the screens. The matters intercepted in this way are taken to the destructor to be burnt.

After leaving the detritus tanks the sewage is conveyed by a channel of considerable length to the precipitation tanks. Across this channel and immediately at the west end of the screening tanks is the chemical mixing-house; the upper floor of this house is reserved for the storing of chemicals, etc. On the ground floor are two grinding mills in which to prepare lime or other precipitants, should they be employed. There is also on the ground floor an electric motor of 10 horse-power, which works the grinding mills, screens and elevator and conveyors.

The chemicals used are aluminoferric and ferrozone. The cakes are placed in cages in the channel between the screening tanks and the mixing-house, where they are dissolved by the action of the sewage and thoroughly mixed by a pair of agitators placed in the conduit. The precipitation tanks are circular, 24 feet in diameter and 20 feet deep. On the outside of each tank is a channel into which the sewage is first received. In this channel are six cast-iron pipes, all carefully turned and set level. The sewage flows over the periphery of each pipe in a very thin sheet and is conveyed to the bottom of the tank. Immediately on its arrival the treated sewage commences to deposit the sludge, and the clarified effluent rises to the top of the tanks, overflows in a very thin sheet into a series of steel channels, and is then led by a conduit to be further treated in the contact beds.

The contact beds are filled with coke and engine ashes. After being charged the sewage is allowed to remain in contact for about two hours. It is then run off into the channel conveying it to the river, the bed is allowed to stand two hours to aerate, and is then refilled. Preparations are in hand to increase the number of tanks and contact beds, and ultimately it is intended to have a double contact. This completes the cycle of treatment of sewage proper; there is still the sludge to deal with. The sludge deposited at the bottom of the precipitation tanks is extracted by syphonic action through a perforated arm, which is caused to revolve just clear of the bottom of the tank, the outlet of this pipe being at a lower level than the top water of the tanks. The sludge then gravitates through pipes and along an underground sludge channel on the west front of the main building to a sump opposite the engine house. From this sump the sludge gravitates into the ejectors, which are of the Shone type, worked by compressed air, by which it is lifted into a high-level tank on the south side of the main buildings. The sludge then gravitates to the press, where on its way to the sludge rams placed in the chamber below the floor it receives a quantity of milk of lime, and being passed through a mixer the sludge and lime are thoroughly incorporated.

From these rams it is forced by compressed air into the sludge presses on the upper floor. These presses are of the usual type, consisting of a series of flat cast-iron filtering cells lined with filter cloth and mounted on horizontal steel bars with arrangementa for screwing the plates tightly together when in use. Provision is made for the admission of the sludge into each of the 40 cells of one set simultaneously under the compressed air pressure of 100 pounds per square inch.

When the presses are opened the cake falls on to a conveyor belt traveling under the presses, and is discharged either through a disintegrator and into a hopper where carts may be loaded or on to other conveyors communicating with the pressed cake store, or to the destructor. In order better to prepare the sludge as a fertilizer, a Tatham's patent sludge disintegrator has been erected, to break up the cakes so as to assume the form of a fine garden mould.

The destructor consists of six cells or furnaces. The cells are built in a compact block, and are fed from the top. The destructor is guaranteed to burn about 60 tons per day of the ordinary house refuse of Bury, mixed in the proportion of one-half to two-thirds house refuse and the remainder sludge extracted from the sewage.

In order to produce the high temperatures, forced air draught has been adopted. There is a special flue arrangement to ensure complete combustion of all noxious gases. The forced air draught is provided by a high-speed engine, coupled direct to a fan, which supplies the necessary quantity of air to the fires, which air on its way thither is heated by passing through hot chambers provided in the interior of the destructor, so that the effect of a hot blast is produced. The fan derives its air from the upper part of the building, thereby ventilating and purifying this, notwithstanding the objectionable material which is constantly being brought to the destructor to be burnt. The hot gases from the destructor are utilized to raise steam in two 200 horse-power Babcock & Wilcox water-tube boilers. Mortar mills are provided to grind up the clinker, which can be used to advantage in making lime mortar. The cost of the disposal works was $224,000. They were designed by Mr. Joshua Cartwright, M. Inst. C. E., and were erected under his supervision.

The Asphalt Plant of Winnipeg, Man., which has been operated by the city for three seasons, now requires some renewals and additions, according to the last report of City Engineer H. N. Ruttan. It is expected that by the contemplated improvements a saving of at least 10 cents per square yard in the cost of the pavement can be made. During 1901 51,252 square yards of asphalt pavement were laid by day labor at an average total cost of $2.78 per square yard.

Stream Pollution Enjoined in New Jersey.

Decision of N. J. Court of Chancery in State ex rel. Board of Health v. Diamond Mills Paper Co.; written by Vice-Chancellor Stevens. Somewhat condensed from 51 Atl. Rep. 1019.

This is a bill filed in the name of the State, on the relation of the State Board of Health, for an injunction to prohibit the defendant from discharging its factory refuse into the Rahway River. The bill is filed under the fourth section of the act of 1899 entitled "An act to secure the purity of the public supplies of potable waters in this State." The act provides as follows: "No sewage, drainage, domestic or factory refuse, excremental or other polluting matter of any kind whatsoever, which either by itself or in connection with other matter will corrupt or impair or tend to corrupt and impair the quality of the water of any river, brook, stream or any tributary or branch thereof or of any lake, pond, well, spring or other reservoir from which is taken or may be taken any public supply of water for domestic use in any city, town, borough, township or other municipality of this State, or which will render or tend to render such water injurious to health, shall be placed in or discharged into the waters . . . of any such river, brook, stream or any tributary or branch thereof or of any lake, pond, well, spring or other reservoir, above the point from which any city, town, borough, township, or other municipality shall or may obtain its supply of water for domestic use." The proviso is that the section quoted shall not be held to apply to any municipality "which at the date of the passage of this act has a public sewer or system of sewers, drains or system of drains, legally constructed under municipal or township authority discharging its drainage or sewage into such river," etc. The act further provides that any penalty for a violation of the act (fixed at $100 for each offense) may be recovered before a justice of the peace in a summary proceeding in the name of the State or local board of health, or that the State Board may institute in the court of chancery the injunction proceedings here under consideration.

Two things are conceded: First, that the defendant does discharge factory refuse into the Rahway River above the point from which the city of Rahway obtains its supply of water; second, that at the point where such supply is taken there is no visible or appreciable deterioration of the water, in so far as observation or chemical analysis can detect it. The distance between this point and the point where the refuse is discharged is six or eight miles.

It is contended that the act is unconstitutional (1) because its title is defective; (2) because it is special and local; and (3) because it attempts to confer upon the court of chancery a jurisdiction which it cannot exercise.

1. Giving the word "secure" the meaning of "guard," "protect," which is one of its ordinary meanings, it seems to me that the title accurately expresses the object. The case is so obviously within the decision of the court of errors in Johnson v. Borough of Asbury Park, 39 Atl. 693, that discussion is unnecessary.

2. It is next contended that the act regulates the internal affairs of towns and counties, and is special and local in that regard. The law is not open to this objection. So far as I have to deal with it, it does not, through the instrumentality of municipal authority, regulate the internal affairs of towns and counties. The prohibition against impairing the waters of the State is imposed by the legislature itself, and not by the municipalities. The subject-matter of the act concerns all the people of the State. Its execution is intrusted to a State board. It is true, as pointed out in Bingham v. Mayor, etc., 40 N. J. Law, 156, and Alexander v. City of Elizabeth, 28 Atl. 51, that there is often conferred upon municipalities the power to legislate locally with respect to like subjects, and, if the legislation were of this character, it would have to conform to the constitutional provision under consideration; but if, as in the case in hand, the legislature chooses to exercise the power itself, it is not, at least, fettered by this restriction.

It is further insisted that the act violates that provision of the fundamental law which declares that the legislature shall not pass special or local laws granting to any corporation, association, or individual any exclusive privilege, immunity, or franchise. This provision, as I understand the decisions, applies only to private corporations. Pell v. Mayor, etc., 40 N. J. Law, 76. The constitution provides that no private, special, or local bill shall be passed unless public notice of the intention to apply therefor, and of the general object thereof, shall have been previously given. As to this provision, the legislature, in conformity with the power expressly conferred upon it, has declared (Rev. St. p. 3197, Sec. 50) "that the publication of any law in the Pamphlet Laws published by the State shall be prima facie evidence, that the notice required by the constitution has been duly granted." This law has been so published, and there is no proof that notice was not given. Freeholders v. Stephenson, 46 N. J. Law, 173. But aside from this objection, I think the law is neither special nor local, within the meaning of this clause. The subject dealt with is the maintenance of the purity of the now existing supplies of potable water.

It is urged that the act is objectionable because it exempts from penalty municipalities which at the date of its passage have legally constructed sewers discharging their sewage into rivers and streams; that it is, therefore, special, because its prohibitions act upon some municipalities, and not upon others, and local, because it exempts from its operation parts of some streams, viz., those into which sewage is now flowing. The argument, of course, goes to this extent: that the legislature has no power, except by private, local, or special bill, of which notice is given, to preserve the waters of the State in their present condition of purity, without exacting the impossible requirement that all water courses, from their source to their mouth, shall be hereafter kept pure and potable. I think that waters which either are, or, under existing law ought to be, pure and potable, may properly be put into a class by themselves. I think, further, that, having regard to the geography of the State, and the shortness of its water courses, the potable waters of the State may be properly classified as those which are above the points of lawful sewage discharge, and the nonpotable as those which are below such points. There is always a possibility that the germs of disease and epidemic may be present in streams and waters of the latter class, however much the sewage and drainage may be diluted; and it is reasonably certain that even if, in some cases, conditions may be improved, the waters below the points of present discharge will never regain their original purity. As to the class of potable waters, the prohibition binds all alike. On the principle on which the courts have heretofore acted, it would seem, therefore, that the potable waters of the State may be classified together as a proper object of legislation. Their marked characteristic is their potability, and the legislation has reference to this characteristic, and tends to perpetuate it. The legislation is within the long line of cases in which it is held that, where the classification is founded upon a substantial difference, it is good. Benson v. Inhabitants of Bloomfield Tp., 33 Atl. 855.

It is next contended that the legislature cannot vest this court with jurisdiction over this matter. All it has done is to give an alternative remedy by injunction. That the legislature may direct the exercise of the injunction power by this court in a new class of cases, to which the remedy is appropriate, seems to me clear. The legislature not infrequently extends the jurisdiction of courts, both of law and of equity, to new cases, and it assigns them to the one court or the other in conformity with the remedy each is accustomed to administer. In the case in hand it must be conceded that the exercise of the injunction power is an appropriate remedy to attain the end in view, viz., the prevention of the pollution of potable waters. It is true that heretofore the rule in equity has been not to exercise its jurisdiction to restrain nuisances unless a serious public injury has been shown to exist—an injury not remediable in the ordinary tribunals. The reason is that the remedy at law has been found adequate. Here, however, we are dealing, not with the jurisdiction ordinarily exercised by this court, but with a jurisdiction conferred by statute. To deny the constitutional validity of the act is to assert that the legislature cannot afford what is undoubtedly an appropriate remedy for a new and threatening wrong; that it may, indeed, punish, but that it cannot prevent.

The next question is whether the defendant has in fact violated the provision of the act. What does the act prohibit? It is first to be noted that what is prohibited may be something less than a nuisance, ordinarily so called. The provision is that "no . . . factory refuse, . . . which either by itself or in connection with other matter will corrupt or impair, or tend to corrupt or impair, the quality of the water of any river . . . from which is taken or may be taken any public supply of water for domestic use in any city, . . . or which renders or tends to render such water injurious to health, shall be placed in the waters of any such river . . . above the point from which any city . . . shall or may obtain its supply of water for domestic use." The language here used is plain and unambiguous. The prohibition is against placing in the water of the river, anywhere above the point from which the city obtains its supply, any factory refuse which will either impair or tend to impair its quality. If at the place of discharge the factory refuse put into the river impairs it, or even tends to impair it, the prohibited act is done.

On this branch of the case, also, State v. Wheeler, 44 N. J. Law, 88, seems to be directly in point. The defendant was indicted for polluting the waters of a brook used to supply a reservoir. The act under which the indictment was framed provided that if any person should throw, or cause or permit to be thrown, into any reservoir, or into the waters of any creek, pond, or brook, the waters of which were used to supply any reservoir, any offal or offensive matter whatever, calculated to render said waters impure, he should be guilty of a misdemeanor. Mr. Justice Magie said: "The question turns on the meaning and relation of this clause, viz., 'calculated to render said waters impure.' What waters are thereby intended—those of the reservoir where waters are collected for distribution for public use, or those of the creek, pond, or brook which supply such reservoir? The grammatical connection of the clause is only consistent with the latter meaning. . . . The whole act plainly shows a design to protect from pollution the waters of creeks used as the feeder for reservoirs for public use, without any reference to whether such pollution appreciably affects the waters when arrived at the reservoir."

The act now under consideration is quite as explicit on this head. I do not understand that there is any question made by defendant that the purity and potability of the waters of the river are impaired at the point of discharge. It is contended that the solids held in suspension in the water as it passes out of the raceway into the river soon sink to the bottom, leaving the water as pure as it was when it entered the mill, but it is not seriously pretended that the waste water at the point of discharge is either pure or potable. The bottled samples demonstrate that it is not.

It would seem plain then that an injunction should issue. The city of Rahway is not shown to have been injured, but this is a bill filed, not by the city of Rahway, which is not a party, but by the State Board of Health. I cannot better state the design of such a statute as that under which the board of health is proceeding than by quoting from Sir George Jessel, M. R., in Attorney General v. Cockermouth Local Board, L. R. 18 Eq. 172. "The defendants are a public body authorized by act of parliament to construct sewage works so that they shall not be a nuisance. Under the powers originally conferred on them, they could not make outfall works outside their district, but a subsequent act of parliament authorized them to go outside. They may now take people's lands. . . . But these powers are subject to this proviso: 'Provided, always, that nothing herein contained shall give or be construed to give powers to any local board to construct or use any outfall drain or sewer for the purpose of conveying sewage or filthy water into any natural water course or stream until such sewage or filthy or refuse water be freed from all excrementitious or other foul or noxious matter such as would affect or deteriorate the purity and quality of the water in such stream or water course.' I do not mean to say that clause might not by possibility have been better drawn, but I think the meaning is pretty plain, and it means this: 'You shall not send your sewage into a natural stream until you have made it wholesome water—until you have got rid of all the noxious matter in it.' That, I think, is the effect of the clause; and, if that is the meaning, the next point is, what water is it that is not to be affected or deteriorated? You are not to affect or deteriorate the water in the river. What portion of the water? I cannot accede to the argument of the defendants that it merely means that you must not poison the whole river. For a river may be hundreds of miles long. I think it must mean that you are not to affect or deteriorate the water in the river at the point where the outfall is, and that, if you at that point pollute the water, you shall not enjoy the privilege given you by the act of parliament of making an outfall outside of your district. . . . Then this is an information by the attorney general against a public body to enforce the terms of a public act of parliament. Now, if I understand the law upon this subject, it is not necessary for the attorney general to show any injury at all. The legislature is of the opinion that certain acts will produce injury, and that is enough. The case I have already referred to, of the attorney general against the Oxford, Worcester & Wolverhampton Railway Company, is in point. There the attorney general would not even answer the affidavits of defendants to show there was no injury caused by the proceedings they were adopting. The legislature is of opinion that it is desirable to preserve our streams in at least their present state of purity. It therefore has said, 'You shall not affect or deteriorate the water at all,' and that the court must assume that the deterioration of the water is an injury which is prohibited for good and sufficient cause. Again, if I look at the evidence in the case, I can see very good reason for the course adopted by the legislature. We had the evidence of scientific men to this effect: that there is always a probability of danger when sewage matter is thrown into a stream, because people may drink of that stream, and, if an epidemic disease is prevalent in a town from which the sewage matter proceeds, that disease may be communicated to the inhabitants of another. Well, that alone would be sufficient justification for the legislature, if it entertained that opinion, inserting this enactment in the act of parliament. That being so, I think I am bound, as regards the information, to grant an injunction to restrain the defendants infringing the provisions of the act of parliament."

I am of opinion that the Board of Health are entitled to an injunction.

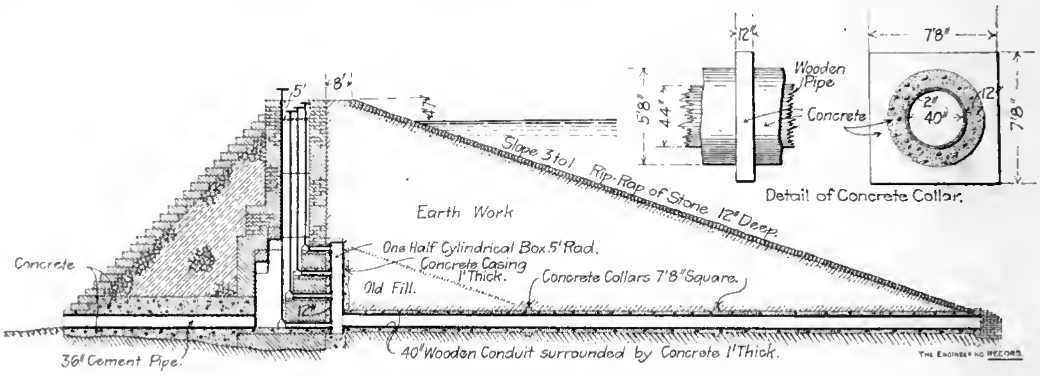
Reconstruction of the Castlewood Dam.

The Castlewood dam, near Denver, Colorado, together with the adjacent property has been purchased by the Denver Sugar Land & Irrigation Company and extensive repairs are now being made on the structure. The construction of this dam was described in The Engineering Record of December 24, 1898, by Mr. A. M. Welles, its designer, and in the issue of May 19, 1900, an account was given of some rather serious leaks which had occurred just previously. At that time the State Engineer ordered the dam to be emptied and kept empty until thoroughly repaired.

To review briefly the facts stated in those articles, the dam as originally built consisted of a masonry retaining wall 600 feet long, 70 feet high above the surface and 4 feet thick at the top. It was battered 10 on 1 on the water face, and was vertical on the other, against which dry rubble was dumped. The downstream face of this rock-fill was covered with large blocks of stone forming a series of steps. The foundation was a dense sandy clay, 5 to 22 feet below the natural surface. A rollway 100 feet long in the center of the dam, and a spillway 40 feet wide at one end was provided for overflow water. The valve chamber was built in the dam proper, and eight 12-inch iron pipes led to it at four different levels through the low earth fill which was placed against the water face some time after the dam was completed. It was stated that this earth fill was carried up somewhat more than half the height of the masonry wall. A 36-inch concrete conduit carried the water from the valve chamber through the rock-fill to the downstream face of the dam.

On April 30, 1900, as a result of a heavy rainfall, it was reported that 500 cubic feet of water per second were passing over the rollway and through the by-pass, the discharge pipes being of course wide open. In some manner the water found a way through the masonry wall and poured in a large stream out of the cracks in the stepped downstream face at about 30 feet from the top of the dam.

Mr. William C. Johnston, president of the Denver Sugar Land & Irrigation Company, states that "the sole cause of the break before was the iron pipes running through the embankment breaking under ground, and part of the flow went under the dam and part through the dam." The use of the iron pipes through the earth embankment, which, as shown in the accompanying cut, is being built up to the full height of the masonry, is avoided in the present plan by laying a single 40-inch wooden conduit reinforced with concrete leading to a steel box also encased in concrete, in which are the entrances to the eight 12-inch pipes through the masonry wall, controlled by valves on the other side. The old spillway, the lower end of which was badly washed out in the flood, is being repaired, and a new one 12 feet wide with 1 to 1 sides is being built at the other end of the dam. The completion of the earth fill will make the structure practically an earth dam with masonry core wall backed by rock fill to give weight. These additions and repairs it is expected will do away with any fears for the safety of the structure.



THE METHOD OF RECONSTRUCTING THE CASTLEWOOD DAM.

The Gallipolis, Ohio, Water Supply is drawn from wells made by sinking 6-foot lengths of 4-foot cast-iron pipe in a sand and gravel bar in the Ohio River. The top of each pipe is about 5 feet below the surface of the bar, at the low-water level, and is covered over so that all the water entering the well must come in at the bottom. The wells are only 12 feet apart, which has been found much too close, but they yield a clear supply no matter what may be the condition of the river water.

The New England Water-Works Association will hold its annual convention on September 10 to 12 at The Brunswick, Boston.

A Large Toll Bridge will be built across the Missouri River at St. Charles, Mo., by the St. Charles & St. Louis Counties Bridge Company. The trusses will be spaced 22½ feet apart on centers, and the space between them will be used at first by a double-track motor road and vehicles, although there will be 10-foot roadways cantilevered out from the trusses as soon as the traffic makes them desirable. The structure includes 145 feet of earth embankment held by concrete retaining walls on the St. Charles side, 525 feet of timber trestle, three 416-foot through spans, a 300-foot through span, and several hundred feet of timber trestle on the east side. The river spans will rest on cylinder piers sunk by the pneumatic process. The structure was planned by Waddell & Hedrick, Kansas City, and the contract for the entire construction was awarded to the Midland Bridge Company of the same city.

Experiments on the Purification of the Springfield Water Supply.

The water supply of Springfield, Mass., has for many years been the source of much concern to the city on account of the large quantity of organic matter in the Ludlow storage reservoir and the consequent rapid growth of algae, notably anabaena, in the warm months, giving the water a very objectionable taste and odor in addition to its high color. In the early spring a further source of trouble sometimes is the presence in the water of great numbers of certain infusoria. In December, 1900, experiments were begun to determine whether sand filtration would be practicable as a means of purifying the Ludlow water, or whether some entirely different scheme of supply would be the best way out of the difficulty. These experiments were concluded in February of this year, and the results are presented in a special report of the Water Commissioners of Springfield, from which the following account was prepared.

For purposes of experimentation a 20x40-foot frame building was divided into two rooms, one for keeping records and for microscopic work, and the other as a general test room for making minor experiments in filtration, chemical determinations, etc. The small filters used consisted of galvanized iron tanks 20 inches in diameter, some 42 inches high and others 6 feet. The two main filters were constructed of cypress staves held together with iron hoops and lined inside with Portland cement mortar plastered over expanded metal lathing nailed to the woodwork. Both filters were carefully covered over so that there was no freezing of the water in them during the coldest weather. The area of each was $^{1}/_{200}$ acre, or about 218 square feet. On the cement floor of each filter was laid a system of open brick drains surrounded with 6 inches of clean gravel 1 to 2 inches in diameter. The successive layers above this were 2 inches of 1 to ½-inch gravel, 1½ inches of ½ to ¼-inch gravel, ½ inch of ¼ to ⅛-inch gravel, and finally 5 feet of sand having an effective size of 0.28 millimeter and a uniformity coefficient of 2.8. This sand is somewhat coarser than that used in the Lawrence, Mass., filter, and was used because a large quantity of it appeared to be easily available in the neighborhood.

One of the large filters was reserved for the reservoir water and the other was used in connection with the so-called canal water before it reaches the reservoir. A 7½x7½x6-inch duplex Deane steam pump supplied the water to two 25,000-gallon tanks, from which it flowed by gravity to the filters except when pumping was taking place, when the water went directly from the reservoir or canal to the filters. The effect of pumping the water was to break up and thoroughly mix the organisms with the water. It did not add to the water any measurable amount of dissolved oxygen. After being in service about 8 months the tanks were emptied and thoroughly cleaned, the deposit of organic matter in each tank being then about ¼ inch in depth. At the end of the experiments, 5 months later, there was only a small accumulation of such deposit.

The condition of the reservoir water during 1901 is stated in the following extract from the State Board of Health's report on the experiments: "The condition of the water in the winter and spring of 1901 was not materially different from its condition at this season in previous years, and the experiments carried on during this time were under conditions such as have usually existed at this season of the year. In the later spring and early summer, on the other hand, the quality of the water was better than usual, and in the months of June and July it was better than has ever been known before during these months. The quantity of organic matter in the water increased rapidly in August, great numbers of anabaena appearing in the water, and from early in August until after the middle of September, a period of about six weeks, the quality of the water was as bad as ever known at this season of the year. After the middle of September, however, the quality of the water improved rapidly and became, during the remainder of the year, much better than it was in the latter part of any previous year."

The principal filter used in the experiments on the purification of the Ludlow reservoir water was "operated, except for a short time, as a continuous filter at a rate of 2½ million gallons per acre per day, and in the latter part of the year at a considerably higher rate, and was successful in removing the objectionable odors from the reservoir water except at the time of the presence of the excessive quantities of organic matter in August and September, when the effluent of the filter had for a time the odor and characteristics of the water of the reservoir and in nearly as pronounced a degree.

"The results obtained by filtering the water through other similar filters at a rate nearly twice as great as that employed during the greater part of the year with the large filter were nearly equal to those obtained with that filter. None of the filters, however, to which Ludlow reservoir water was directly applied removed the characteristic odor during the time in August and September when this water contained excessive quantities of organic matter.

"An experiment upon the refiltration of the reservoir water was begun early in August and continued until the end of the experiments. This experiment consisted in applying the effluent of the large filter to another similar filter at a much more rapid rate. This secondary filter successfully removed the taste and odor from the effluent of the large filter and the effluent of the secondary filter was at all times during the operation of good quality and suitable for the purposes of a public water supply."

During 1901 the canal water flowing into the reservoir contained, according to the Board of Health, "much smaller quantities of organic matter and organisms than were found in reservoir water, and the largest number of organisms were present at a time when the water from Belchertown reservoir entered the canal accidentally. The water of the canal is much more highly colored under ordinary conditions than the water of the reservoir, and a smaller proportion of the color was removed by filtration. The results show that, under conditions similar to those which existed in 1901, objectionable tastes and odors and a considerable portion of the organic matter can be removed from this water by filtration, and the color can be noticeably reduced, so that this water would be of good quality for the purposes of a public water supply, though the color would probably at times be quite noticeable."

The accompanying table taken from the report of Percy M. Blake, consulting engineer to the Water Commissioners, gives the main results of the experiments.

From August 12, 1901, to January 30, 1902, the reservoir water was subjected to a second filtration at the rate of nearly 10 million gallons per acre per day. The average albuminoid ammonia in the effluent from this secondary filter was 0.0098; the maximum 0.0130. The average color was 0.13, and the maximum 0.29. It was found necessary to use aerating devices in order to recharge with oxygen the effluent from the primary filter before applying it to the secondary one. This of itself would greatly complicate plans for the purification of any large amount of water.

NOTE.—Values marked "a" are from experiments June 12, 1899, to March 4, 1902; those marked "b" from February 23, 1901, to January 30, 1902; and those marked "c" from April 10, 1900, to March 4, 1902.

It will be noticed that in the table there are given analyses of the water of Westfield River. These are given for purposes of comparison, as careful surveys have shown this to be by far the best source of supply should it be determined to discontinue the Ludlow reservoir.

Coming now to the financial part of the problem, while it is admitted that a system of double filtration is possible, it would seem to be impracticable on a scale large enough for the supply of a large and growing city such as Springfield, except as a last resort. On this subject the Board of Health is very emphatic: "A comparison of the estimated cost of engineering structures and mill damages for taking water from the Westfield River with the estimated probable cost of filtering the Ludlow and Jabish brook sources and making the necessary additions and enlargements, indicates that the cost of a supply from the Westfield River is likely to be less to the city of Springfield than the cost of a supply from the present sources developed to their fullest capacity, and very much less than the cost of a supply from the present sources increased by water from Swift River, which increase would probably be required within ten years."

Accordingly preliminary plans have been prepared for a dam across the East branch of Westfield River above Norwich bridge, the proposed dam being of monolithic masonry 170 feet long and 60 feet in height above the bed of the stream. The high-water area will be about 77 acres, and the total storage capacity about 360 million gallons. (The total storage capacity of Ludlow reservoir is 2,000 million gallons.) Nearly the whole length of the dam will be required for the safe overflow of storm waters. It is proposed to utilize the surplus water in generating power to partly pay for the damages to mill privileges on the river below.

The experiments outlined above are among the most interesting conducted recently in this country because they have led to a result which is the opposite to the customary outcome of such investigations. Generally it is found that filtration affords a more economical means of procuring a satisfactory supply than the construction of works for bringing to a city the waters of some distant stream or lake. The fact that the experiments with the Ludlow reservoir supply have shown it to be unsuitable points definitely to the best sources of the new supply for Springfield, and the fixing of that fact beyond reasonable expense is well worth the expense of the investigation. From the historical point of view this decision is of much general interest, for the Ludlow reservoir has been for years one of the "habitual criminals" of the water-works world. It has been the subject of many special reports, a field of investigation of a number of specialists in water analysis, and the despair of the local water commissioners.

Duty Test of a 6,000,000-Gallon Pumping Engine, Haverhill, Mass.

A duty trial of a 6,000,000-gallon pumping engine showing very good results was conducted last fall in an interesting and rather unusual manner at the new Kenoza pumping station of the Haverhill, Mass., water-works. The machinery was furnished by the Barr Pumping Engine Company, of Philadelphia, under a contract which called for a horizontal, cross-compound, fly-wheel pumping engine having a capacity to lift 6,000,000 gallons in 24 hours a total of 215 feet, including friction in the force main and a possible suction lift of 25 feet; two horizontal tubular boilers each having a shell 6 feet in diameter and 140 3-inch tubes, 16 feet long, and the necessary heaters, feed and air pumps and a jet condenser. The contractor gave a guaranty that the whole plant should have a duty of 105,000,000 foot-pounds per 100 pounds of coal, with no allowance for ashes and waste, the coal not to contain more than 2 per cent. of moisture. The conditions under which the plant should be run in the test were stated as follows: The plant should be started cold; the boiler fired up and the plant run for 10 hours out of the 24 for four consecutive days, banking the fire each night, except the last. All the fuel used should be charged against the test, including wood used in starting, three pounds of wood being considered as equivalent to one pound of coal. The conditions are practically the same as those of the actual running of the plant in regular service. The steam pressure was not to exceed 150 pounds.

A type of reheater designed by Mr. F. W. Dean, of the engineering firm of Dean & Main, of Boston, is used, taking the place of the usual form, which heats the exhaust steam from the high-pressure cylinder before it enters the low-pressure cylinder by means of live steam from the boilers. The Dean reheater is placed in the smoke flue from the boiler to the chimney and utilizes the escaping gases to heat the exhaust from the high-pressure cylinder.

As to general dimensions of the pump, the diameter of the right-hand plunger is 16¼ inches, that of the left-hand, 16 9/32 inches. The length of stroke, 35 27/32 inches; diameter of plunger rod, 3½ inches; net effective area of plunger, 202.99 square inches; total displacement per revolution, 29,092.99 cubic inches, equivalent to 125.51 gallons; net displacement less 1½ per cent. for slip, 124.05 gallons.

The test was undertaken by Mr. Freeman C. Coffin, of Boston, the consulting engineer retained by the Board of Water Commissioners of Haverhill to design the works, and Mr. W. H. Bodfish for the contractor. In his report of the test, Mr. Coffin says that arrangements were made to begin on the morning of August 28, 1901. It was found at that time, although the fire had been drawn for several days, that the water in the boiler was still hot, having a temperature of 160 degrees Fahrenheit. As the postponement would have made considerable additional expense, it was decided to compute the weight of coal required to raise the boiler and the water in it from the temperature of the water in the lake, namely, 70 degrees, to 160 degrees and add this to the actual coal consumed. It was also found that the steam pressure on another boiler (20 pounds) had been on the jackets of the engine all night and the whole of the steam cylinders were heated. The weight of coal added to that actually consumed on account of these corrections was 459 pounds, made up as follows: To raise the temperature of the water in the boiler, 158 pounds; of the metal in the boiler, 23 pounds; of the setting, 175 pounds; and of the engine, 103 pounds. The principal results of the tests for the four days, together with the results for the entire test, are given in an accompanying table.

Results of Four Days' Duty Trial.

Duration, hrs.	Total coal, lbs.	Gals., millions.	Lift, ft.	Duty, million ft.-lbs.	Gals. per lb. coal.	Developed H. P.	Coal per H.-P.-hr., lbs.

Duty per 1,000 lbs. steam; million ft.-lbs.	150.796	149.389

Although no allowance was made for ashes, they were weighed and found to be 8.65 per cent. of the total coal used. A record was kept of the coal used for the different purposes of starting, running and banking, which, though not strictly accurate, Mr. Coffin reported, is interesting as showing what proportion of the total was required for each purpose, and as showing the duty which was obtained under the conditions of an ordinary test, that is, while actually running. On the basis of the entire test of four days, 14.3 per cent. was used in starting, 82 per cent. for running, 3.7 per cent. for banking. If the average amount used for starting when the fire was banked were substituted in the first day, and the average amount for banking were added in the last day, the condition of every day's running would be approximated and the percentages would be as follows: Starting, 8.6 per cent.; running, 86.1 per cent.; banking, 5.3 per cent. That is, in a plant run 10 hours every day under the stated conditions the coal used for banking and firing would be about 15 per cent. of the total. For these figures, Mr. Coffin also calculated that a duty of 137,000,000 foot-pounds were obtained per 100 pounds of coal used in actual running time.

After the tests described were made, two other tests were made for the Barr Pumping Engine Company by Messrs. Dean & Main, in which the duty was based on the steam used in the engine instead of on the coal consumed under the boilers. In these tests, the results of which are also given herewith, an average duty of 150,092,000 foot-pounds for each 1,000 pounds of steam was obtained. Mr. Coffin concluded that if it is assumed that the engine was doing about the same duty in the test of the entire plant, based on coal consumption, as in that of the engine alone, based on steam consumption, the performance of the boiler can be obtained by a comparison of the results of the tests, using the duty based on the coal used in the actual running time, thus:

$$\frac{137{,}000{,}000 \div 100 \text{ (coal)}}{150{,}000{,}000 \div 1{,}000 \text{ (steam)}} = 9.13.$$

That is, 9.13 pounds of water evaporated for each pound of coal consumed under a pressure of 145 pounds with feed water at approximately 135 degrees, or an equivalent evaporation from and at 212 of 10.3 pounds.

A Concrete Retaining Wall 9 feet high and 2 feet wide at the base was built at Sea Girt, N. J., to retain a mass of sand at some rifle-range butts. The concrete was strong and hard but the dimensions of the wall were so slight that about 125 feet of it was pushed over, killing three men.

The Mechanical Plant in the Rogers Peet Building, New York.

Rogers, Peet & Company, a New York clothing firm, have recently moved one of their stores to a new building at the corner of Broadway and 13th Street, in which an interesting mechanical plant has been installed. The structure is eight stories high and of fire-proof construction. It is lighted by both arc and incandescent lamps, and is equipped with complete fire apparatus, including an automatic sprinkler system. A considerable amount of current is demanded throughout the building for lighting and power purposes, the latter for running motors for fans, a coal conveyor and the machines in a cutting department. Electricity is also used to heat a number of flat-irons in the pressing establishment on the basement floor. A pneumatic cast system, inter-room and general telephone services, heating and ventilating plants, and a hydraulic and electric elevator apparatus are part of the general outlay. In addition to the steam used in the heating and power apparatus there is a certain amount used in a cloth steaming outfit on the seventh floor, which is somewhat similar to a French mangle arrangement, and also in several cookers in a restaurant on the eighth floor, provided solely for the convenience of the employees of the building.

The building itself is of irregular shape, facing on Broadway for a distance of 63 feet and extends along 13th Street to Fourth Avenue, covering an approximate area of 20,000 square feet. It is of steel-skeleton construction and is fitted with the most modern improvements. The first floor is of course used as the main sales floor and is without any partitions. A small mezzanine story is located in the rear of this floor and is used by the wrappers. Two or three sales departments are contained on the floors above, which are arranged in much the same way. As mentioned, the steaming-room and space for the storage of cloths is on the seventh floor, while on the above floor there is a restaurant and a large cutting department. The mechanical plant, a sample department, and the pressing department equipped with about 35 electric irons, occupy the basement.

The steam plant includes three Babcock & Wilcox water-tube boilers, located on the north side of the basement. Two have a capacity of 200 horse-power and the other is of 150 horse-power; all three are fitted with McClave shaking grates. Coal for the furnaces is carried from a chute on the side street to a vault with a capacity of about 200 tons, by means of an electrically driven Robins belt conveyor. The motor for this is situated in a vent shaft near the bunkers for the purpose of keeping it away from the heat of the boiler room. In front of the boilers, a trolley is rigged with a bucket for conveying ashes to a pit. The boilers are built to stand a pressure of 200 pounds per square inch, and the working pressure which is being carried is 110 pounds. Over the front of the boilers, as shown in the accompanying illustration, is a main steam header and over the rear is an auxiliary header. A Potter mesh separator is inserted in each steam drum outlet.

Steam, generally taken from the main header supplied from 7-inch boiler outlets, is carried over into a 10-inch power main serving four generator sets in the engine room. They consist of three 120-volt multipolar compound-wound Western Electric dynamos of 75 kilowatts capacity and one 50-kilowatt unit of the same type, which are direct-coupled to 15x14-inch and 13x12-inch Payne single expansion horizontal high-speed engines, respectively. At a point in the power main a little in advance of where the first engine is taken off, there is inserted a Bundy steam separator which is trapped back to a drip tank. Steam is also supplied to two boiler feed pumps, each 7½x4½x10 inches in size, of the Worthington type, located as shown on the plan, which pump water of condensation from the heating system, first through a Ward filter for removing grease, and then through a 550-horse-power Berryman feed-water heater to the boilers. The pumps are operated in connection with a governor to insure automatic working, and are cross-connected to a house pump, so that the latter may be used as an auxiliary feed pump.

Among other steam apparatus is a 5¼x3½x5-inch duplex pump of the same make, which, also automatically governed, drains a blow-off tank 42 inches in diameter and 8 feet long, tested to withstand a pressure of 150 pounds per square inch. Within the tank is the usual cooling coil composed of 100 feet of 2-inch brass pipe, for cooling the waste water before its discharge into the sewer by means of an indraft of fresh feed water from the city mains. There is also an additional coil of 500 feet of the same size pipe to be cooled by the air, when necessary or desirable. Two other Worthington pumps are located in the farther end of the engine room. One is used as a house pump which is 12x6x10 inches in size and is connected to a tank 10x8x7 feet. The other is a 12x6x12-inch fire pump, with which the house pump is cross-connected.

The electrical equipment comprises the dynamos mentioned, a switchboard, motors for several fans, the wiring, etc. A two and three-wire system is provided and an Edison circuit is brought into the building. In the case of the three-wire lighting circuit the middle or neutral wire is, as usual, of the same current carrying capacity as that of the two outside wires. No more than eight incandescent lamps are placed on any branch circuit and only one arc light. The arc lamps used are of the Manhattan direct current 120-volt enclosed type. There are about 2,000 incandescent lamps throughout the building and approximately 450 arc lights. In the ironing room each iron is connected to a small panel board from which the current is governed, each iron taking about 7 amperes.

The main switchboard, which is situated at one side of the engine room, is 17 feet long by 11 feet high. It is composed of six panels of white Italian marble and stands clear of the wall by about 8 feet, the space between one end and the wall being barred by a heavy bronze wire netting, and the other by a door of similar material. The instruments carried on the board are as follows: Two voltmeters, four ammeters and three Thomson recording wattmeters, two of 600 amperes capacity and one of 400. There are 40 different switches for controlling various circuits, and four double-pole circuit-breakers of the same current capacity as the wattmeters, for the dynamos. Four pilot lamps are also contained on the board for the dynamos as well as for rheostats of the Ward-Leonard make. There are three general centers of distribution in the building, one for the central portion, one for the eastern section and another for the western. This arrangement necessitates three sets of switches on the switchboard, each set controlling the panel boxes on each floor. The Broadway floor is controlled independently. The panel boxes are fitted throughout the house with bases of white marble, on each of which space is left for two extra branch circuits. All generator feeders to switchboard have been run in loricated conduits laid under the floor in wooden trenches filled with tar. The maximum load, which has been carried on the lighting and power circuits since the plant has been in operation, is 1,800 amperes.

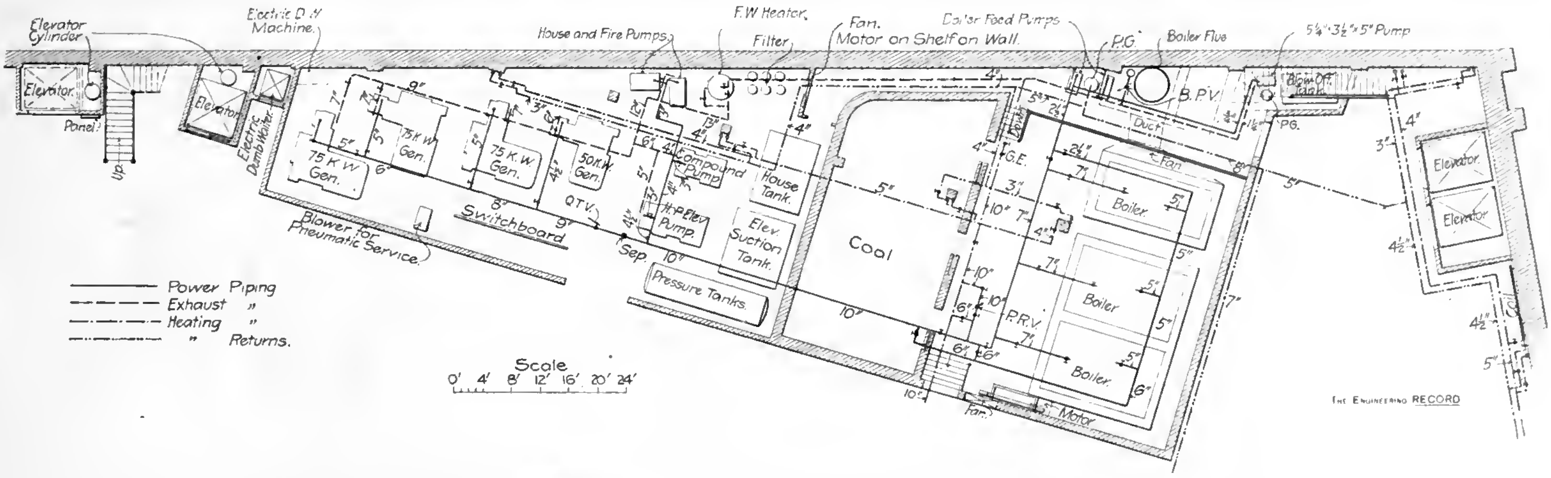
The ventilation of the structure is accomplished entirely by natural means, with the exception of the basement, boiler and engine rooms, where disk fans and duct work are installed. One ventilating duct, with a 40-inch Seymour disk fan within, is run from an inside partition wall of the boiler room to the base of a ventilating flue. Two other Seymour fans, each 60 inches in diameter, are also installed for the ventilation of both rooms. The fans are belted to Western Electric multipolar shunt motors of 5-horse-power each. The ventilation of a 40x50-foot steam room on the seventh floor is accomplished by means of two 30-inch disk fans, one placed in each window of the room.

Direct radiation is installed throughout the building with the exception of the main floor, where floor registers discharge warm air from twelve heating stacks. There is a single register to each stack, the latter being suspended from the ceiling of the basement. Exhaust steam from the engines and pumps is used in the heating system. A back-pressure valve allows exhaust steam to pass upward to the roof through a 10-inch pipe when the back-pressure becomes excessive. Live steam may be used for heating when necessary. From the basement system of heating mains there are taken off nineteen steam and return lines from 2 to 4 inches in size. Returns have been made in general one size smaller than the corresponding supply risers. A ½-inch air line is run in connection with each pair of vertical lines and all lead into a 1-inch main air line in the basement draining into a slop sink. The total amount of radiation is about 21,000 square feet. On the top floor steam coils have been suspended from the ceiling, giving more floor space and counter-balancing the skylight surface.

The elevator equipment, comprising a 14x20x10x12-inch Epping-Carpenter compound pump, an 18x10x12-inch high-pressure pump of the same type, tanks, etc., is installed near the engines. There are six passenger hydraulic elevators and one electric elevator for the transference of material. The suction tank for the elevators, 10x10 feet in plan and 7 feet in depth, is of about 15,000 gallons capacity, and is located in close proximity to a 10,000-gallon pressure tank, supported on pedestals. The hydraulic elevators have a carrying capacity of about two tons and are designed to travel at the speed of 400 feet per minute.

The sprinkler fire system installed is extensive. Two pressure tanks are located in an enclosure on the roof. Each is 35 feet long and 7 feet in diameter, being generally filled to about three-quarters of its capacity. The water is kept under a constant pressure of 75 pounds per square inch, which is maintained by a small vertical duplex air compressor on one of the walls of the engine room. The same pressure exists in the piping for this system, which has been fitted with Grinnell automatic sprinklers. Electric gauges connected to the pressure tanks register the pressure present in them, making and breaking a circuit controlling the compressor in the basement, and operating upon a fluctuation of two pounds above or below the required pressure. The tanks are connected to a 10-inch standpipe dropping to the basement which has two branches, one for the eastern side of the building and one for the western. A city fire alarm box is installed in the building and there is also a house system. A roof gravity tank may be used in place of the fire pressure tanks in case of an emergency, the water being kept from freezing by a coil of steam piping within. The tanks have intermediate connections which are provided with check valves as usual.

While there is no water-cooling machinery installed in the building, ice boxes made by the Lorillard Refrigerator Company, of New York, are provided, two to each floor. The cutting department is located on the top floor and the cutting machines are run from small Lundell electric motors supplying power through flexible shafting to the cutting wheel of each. On the floor below, four cloth steaming machines made by the Hebdon Machine & Finishing Company, of New York, the steel cylinders of which are 8 feet long and 18 inches in diameter, take high pressure steam. A cash system has been installed by the Lamson Consolidated Store Service Company, of Lowell, Mass., and a blower made by the Connersville Blower Company, of Connersville, Ind., is located near one end of the switchboard for maintaining an air pressure throughout the system of tubing. There are thirty interior telephones in the building,



THE ARRANGEMENT OF THE MECHANICAL PLANT IN THE BASEMENT OF THE ROOERS-PEET BUILDING.

which were installed by Stanley & Patterson, of New York.

The architects for the building, which is owned by Mr. W. W. Astor, were Messrs. Clinton & Russell, of New York, and the plant was designed by Col. J. Hollis Wells, their engineer. The general contractor was Mr. John Downey. The contractors for the heating and mehcanical equipment were Baker, Smith & Company, of New York, and the electrical installation was furnished by the Western Electric Company, of New York.

The Grand Avenue Bascule Bridge, Milwaukee.

The Grand Avenue highway bridge at Milwaukee carries a large traffic at a low level across the Milwaukee River, on which navigation must be maintained for tugs and vessels. The banks of the river are curved at this point and are about 200 feet apart between the docks which line them. The bridge connects Grand Avenue on one side of the river with Wisconsin Avenue on the opposite side; these streets make small angles with the river and with each other and their center lines are more than 50 feet apart in the center of the river so that the structure is skewed in every direction. The old bridge was a swing span 180 feet long from out to out, as indicated by dotted lines in the general plan. It was supported on a center pier about 40 feet wide and 220 feet long in the direction of the river; this left a minimum space of less than 60 feet between each abutment and the center pier and compelled all boats to pass through a long and crooked channel. For the new bridge it was determined to provide a wider, shorter, straight channel and dispense with the center pier, and this was done by the adoption of a bascule with two leaves mounted on trunnions and operated by rack and pinion gears.

The new structure has a total width of 64 feet and a length of 180 feet, and consists of two stationary and two movable parts. The movable parts are about 69 feet long over all and revolve on horizontal axes about 21 feet from the shore ends. They have floor platforms about 60 feet long, meeting in the center line of the bridge and carry a 36-foot roadway and two sidewalks about 12 feet wide in the clear. When open the bridge affords a clear center channel opening which for 65 feet opposite the abutments, has a minimum width of 95 feet in the line of the axis, 70 feet in the direction of the river, these widths being rapidly increased both sides of the abutments.

The fixed approach spans from the old abutments to the new piers have two lines of deck lattice girders and the channel spans have two lines of half through revolving cantilever plate girders. There are four 16x32-foot piers, each of which supports one approach girder and one cantilever girder, or one-fourth of all the superstructure which is not carried by the abutments. Heavy vertical steel columns are built into the piers and extend above their tops to carry the pivots which support the cantilever girders and around which the shore ends revolve into slots in the masonry when the bridge is open. The bridge requires no clearance for operation beyond either side or either end, all the operating machinery is located under the bridge floor and when the bridge is open no part of it projects above the clear channel space between fenders.

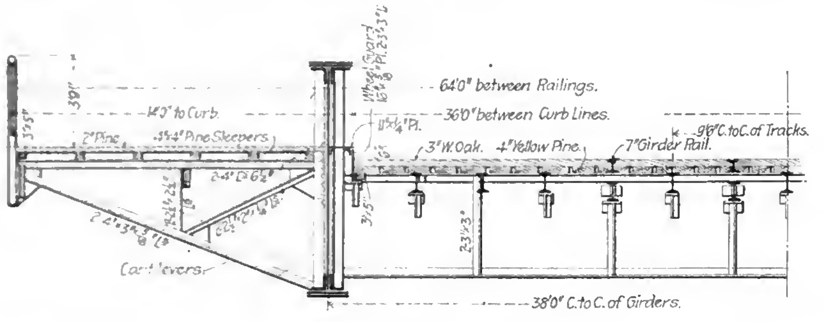
The four piers are symmetrically arranged about the center lines of the bridge and are duplicates, except that two of them have one corner beveled for clearance to navigation. The rectangular piers are supported on 106 and the other piers on 102 piles each, and are built of concrete laid inside a sheet pile permanent cofferdam. Under the pivots the piles are driven in staggered rows 21 inches apart, elsewhere they are 3 feet apart on centers. They are not less than 45 feet long, 9 inches in diameter at the tip and 14 inches at the butt. The outer rows were cut off at about high-water mark and supported a 12x12-inch guide frame in which Wakefield sheet piles, 9 inches thick and 30 feet long were driven to form a cofferdam with the upper edges braced by 8x12-inch white oak horizontal waling pieces and tie rods. The cofferdams were braced inside, pumped out and the piles cut off 20 feet below water level. The earth was excavated 2 feet below the pile tops and 1:3:5 Portland cement concrete made with 2-inch broken stone was rammed in to a general level of 1½ feet below water line, wells being left in all the piers for the tail ends of the girders.

The front fenders each have two rows of white oak piles about 2 feet apart with the piles 30 inches apart in the rows. They are cut off 7 feet above water level and are faced on the insides to receive, above water line, two lines of 12x12-inch white oak waling pieces bolted between them, 4 feet apart on centers, with a 1¼-inch bolt through each transverse pair of piles. Between the piles in the front row 12x12-inch blocks are bolted to the waling piece to make a continuous outside vertical surface to which a 6x½-inch iron band is attached with countersunk bolts, from end to end of the fender. The ends of the fenders terminate with groups of ten white oak piles fastened together with three turns of a 1-inch chain.

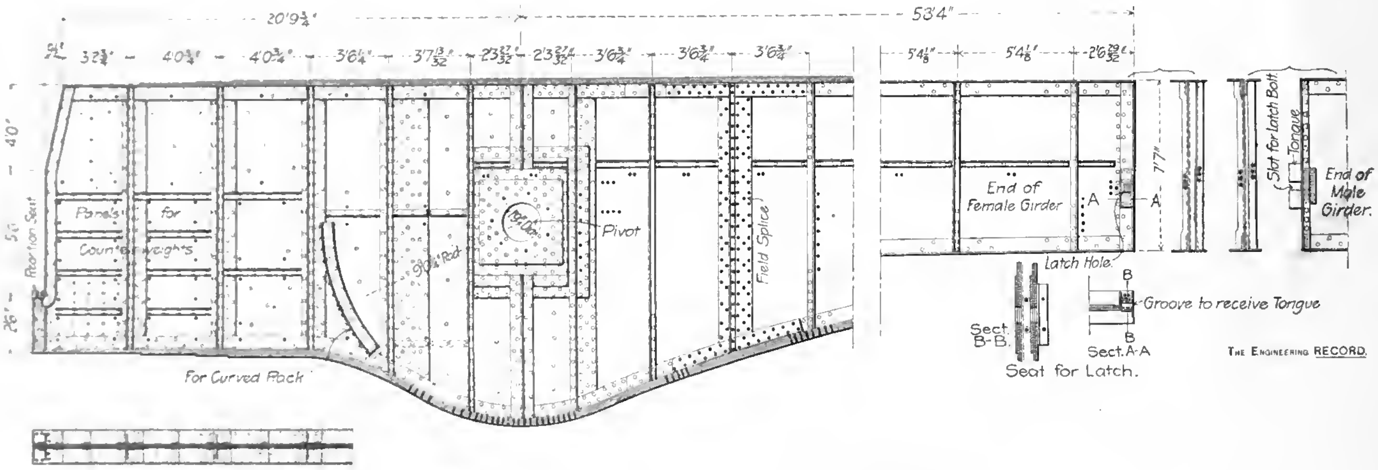
In each pier the concrete was reinforced by eight horizontal lines of 2½x2½x¼-inch angles bedded in it about 2 feet apart vertically, each being bent to a U-shape and extending continuously around the river end and two sides of the pier. There is also a line of 1-inch horizontal anchor bolts from 3 to 5 feet apart which are screwed up on the waling piece at the top of the cofferdam, extend 6 feet into the concrete and are turned down at right angles at the inner ends.

About 4 feet above the pile tops five 12-inch transverse I-beams are bedded in the concrete and extend across the pier to form a footing for the pivot columns. The pivot columns are 24 feet long and are made with four 12-inch channels and two 45-inch flange cover plates. They are seated with extended base plates on the top flanges of the grillage beams, and have the lower ends of each pair connected by a horizontal oak beam in the bottom of the girder well. At the shore end of each pier there are two 24-foot anchor posts, each consisting of a 15-inch channel slightly inclined from the vertical and having riveted across the lower end of the web a transverse piece which takes bearing on a distributing girder under a grillage of 12-inch I-beams bedded in the concrete in a plane at right angles to the anchor post and about 2 feet from the pile tops on the center line of the anchor post.

The superstructure consists of the two bascule leaves and their two approach deck spans. Each bascule leaf consists essentially of a platform about 64 feet wide and 61 feet long which is pivoted on a horizontal transverse axis very near the shore end. It has two main double-cantilever girders 38 feet apart on centers, which project beyond the platform at the shore end to carry the counterweights. The girders are 79 feet 1¾ inches long and 15¹/₈ feet in maximum depth, with horizontal top flanges



Half Cross-Section of Swinging Span.



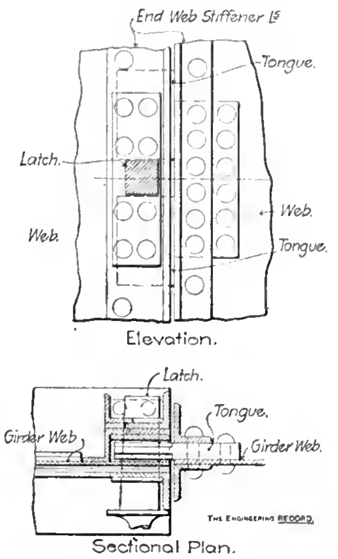
General Features of one of the Bascule Girders.

and curved bottom flanges. They are pivoted on pins 21 inches in diameter that pierce their solid webs 58 feet 4 inches from the extremity of the long arms and about 6 feet below the top flanges. The long arms of opposite girders in the same longitudinal plane meet and when the bridge is closed are locked together over the center of the channel. The short arms revolve downwards into the pier-pits when the bascules are open and when it is closed react against offset seats on the upper sides of the short arms.

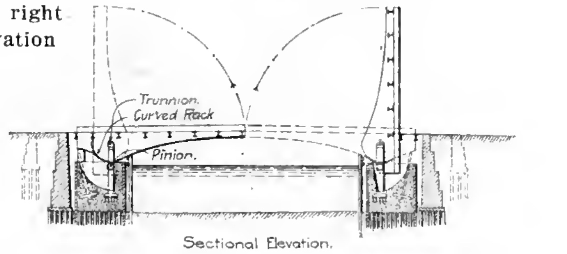
The two main girders in each bascule are connected by floorbeams 8½ feet apart, and by X-brace lateral struts 50-inches deep which have top and bottom flanges made with single 5x3-inch angles latticed together with 2x2½-inch web angles. The top and bottom angles of the struts engage the top and bottom flanges of the floorbeams and virtually form top and bottom lateral systems under the roadway. Cantilever brackets about 13 feet long are riveted to the outsides of the girders to carry the sidewalks and are connected by a system of 4x4-inch zigzag angles in the planes of their top flanges. The roadway stringers are 9-inch longitudinal I-beams about 3 feet apart. The sidewalk joists are 4-inch transverse channels 2½ feet apart. The roadway floor has a lower course of 4x8-inch diagonal yellow pine planks, secured to each stringer with hook spikes, and bottom plates, pockets to receive the cast-iron counterweight sections. These are made in various sizes, all about 20 inches thick, 1½ to 4 feet wide and from 2 to 6 feet high, fitted between the vertical and horizontal web stiffening angles and secured by horizontal bolts through the girder web.

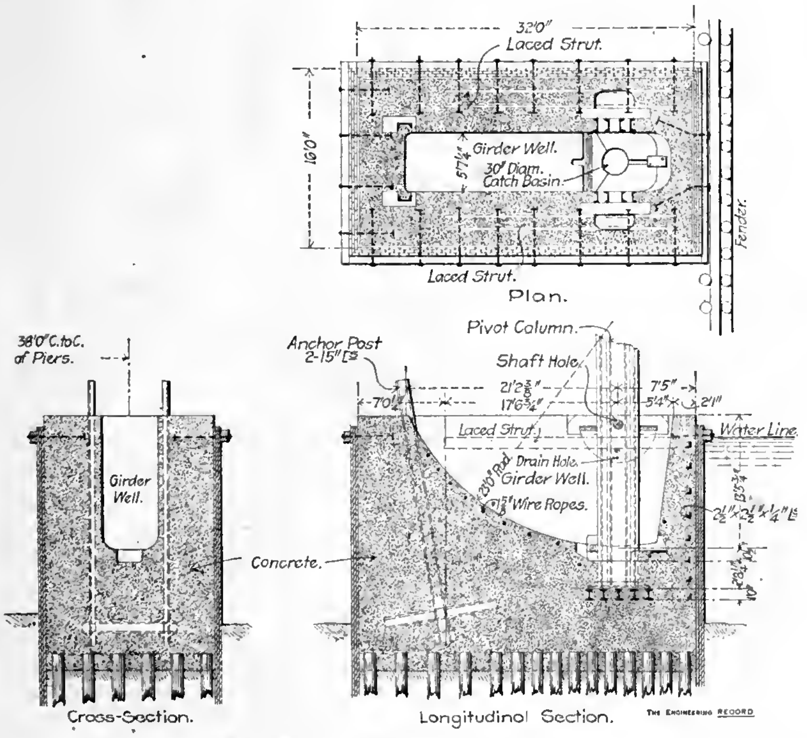
Between the piers at each end of the bridge there is a 50-horse-power electric motor with a transverse horizontal driving shaft which has at each end a pinion engaging a gear wheel keyed to the inside end of a short parallel shaft that passes through the lower part of the pivot column and has a pinion keyed to its outside end engaging the segmental rack on the main bascule girder. By this direct mechanism the bascules can be opened or closed separately or simultaneously in 45 seconds. A two-man hand gear is also provided to operate the driving pinion and swing the leaves if necessary. When closed the bascule leaves are locked together by bolts engaging the adjacent ends of the long arms at mid-span. The bolts do not transmit any stress and the bascules act under both dead and live loads as independent cantilevers, anchored at the shore ends.

The bascule girders are made right and left and the extremities of their long arms are made male and female with reference to the connection details. The female end of the right hand girder is shown in the general elevation ing slightly to the points. The shoulder is attached to the end of a horizontal square guide bar sliding in slots through the stringer webs. It is riveted between top and bottom plates which connect it to the operating bar parallel to it and 6 inches away. One end of it is pin-

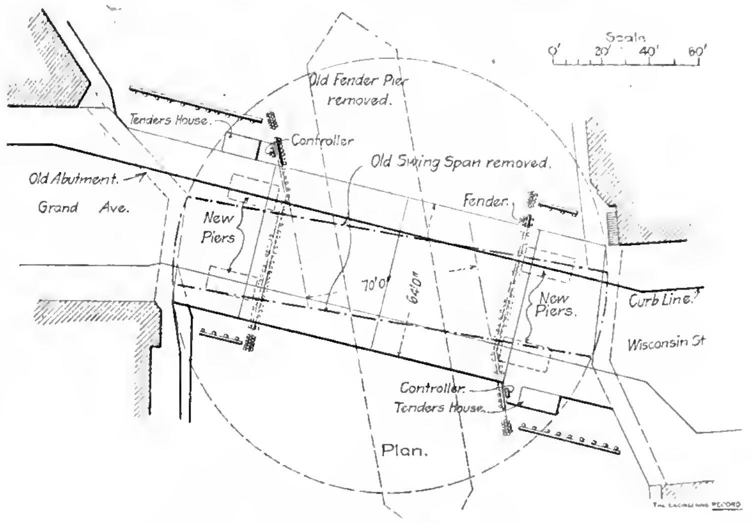


BASCULE LOCK.





PIER SUPPORTING BASCULE GIRDER.



LOCATION OF OLD AND NEW BRIDGES.

an upper course of 3x8-inch transverse white oak planks. The sidewalks are of 2x6-inch transverse white pine planks.

The main girders are made with ⅜-inch web plates, and 8x8-inch flange angles, 18-inch flange cover plates and 3x3-inch vertical web stiffener angles. At the pivot the web is reinforced to a thickness of about 5½ inches for the bearings, and the lower flange is curved around it to a radius of about 9 feet. On this segment and on a continuation of it formed by an angle bent to the same radius and riveted to the side of the web plate, there is bolted a rack by which the girder is revolved with a pinion. At the shore end of the girder, beyond the pivot, 20-inch horizontal plates about 14 feet long are riveted to the upper sides of the bottom flange angles and project beyond them to form a support or case for the counterweight castings. The plate is stiffened by transverse diaphragms or gusset plates riveted across them and to the vertical web stiffeners so as to form, with the and has double end vertical web stiffener angles spaced 2¼ inches apart in the clear as shown in the cross section at A A. The offset vertical web stiffener angle is reinforced with angles and plates so as to form a rigid side for a vertical slot in the end of the girder. The end of the adjacent male girder is similar with lighter end vertical angles between which is riveted a tongue casting with a front projection which, when both bascules are closed engages the slot in the female girder. It has a horizontal slot across the middle which corresponds with a square horizontal hole through the web and end angles of the female girder. A square horizontal bar can be passed through the hole in the female girder and the slot in the tongue of the male girder and lock both girders together as indicated in the sketch of the assembled latch. The bearings for the tongue and latch are fitted with a slight clearance and are ground smooth. Each of the two latch bolts is about 8 inches long and 4 inches square at the shoulder, taper- connected to toggle bars in a horizontal plane which are operated by the short arm of a lever, the long arm of which is moved back and forth by a longitudinal horizontal gas pipe worked by a lever in the operating house. There is also a simple heel latch at the shore end of each leaf. It is merely a wooden strut hinged at the bottom and arranged to have its top jammed tight against bottom chord of the girder when closed. Each leaf has also at the heel two rods running up to dashpots on the adjoining fixed approach span.

From the abutments to the pivots the floor platform is carried over the piers and the river on deck girders. Those which connect the anchor and pivot columns are lattice girders with special ends, having the upper sides of the river ends notched for clearance with the bascules. The I-beam stringers support a roadway floor of 5/16-inch buckle plates convex side up which are covered by asphalt pavement on a concrete base. The stationary sidewalks have

5/16-inch buckle plates, concave side up, covered with 2 inches of 1:2:5 Portland cement concrete finished with 1 inch of 1:1 Portland cement and fine crushed granite. The sidewalks have steel curbs and substantial hand rails 3 feet 9 inches high which weigh 30 pounds per lineal foot. At each end of the bridge there is, on an extension of the stationary sidewalk, on opposite sides of the street, an 8x15-foot wooden operating house.

The bridge is figured for live loads produced by uniform loading and by two electric cars, one on each pair of 7-inch girder rails, and moving in opposite directions. Each typical car is 43 feet long and 8½ feet wide, weighs 55,000 pounds, and is carried on two trucks 17¾ feet apart with 6-foot wheel bases. The roadway outside the tracks and the sidewalks is assumed to be loaded to 100 pounds per square foot. Wind pressure is assumed to be a moving load of 400 pounds per lineal foot applied at floor level. A wind pressure of 25 pounds of exposed surface is assumed when the bridge is opened and the machinery is proportioned to operate it in any position under such pressure. The counterweights are calculated to be proportioned and arranged to balance exactly the revolving leaves in any position and enable them to remain stationary without the use of the brakes.

All principal members are made of medium steel with a tensile strength of 60,000 to 68,000 pounds per square inch. The allowed stresses in pounds per square inch are: For tension, lateral and sway bracing, 18,000; I-beams, 13,000; girder flanges, 13,000. Shop rivets are proportioned for 15,000 pounds bearing and 7,500 pounds shearing stresses and field rivets for 12,000 and 6,000 pounds respectively. The bed plates are laid in Portland cement and are proportioned for a pressure of 35,000 pounds per square foot on the masonry.

The bridge was designed and constructed under the general direction of the Commissioners of Public Works of Milwaukee, by the Wisconsin Bridge & Iron Company of that city. Mr. Charles J. Poetsch, city engineer, and Mr. B. W. Perrigo were in general charge for the city.

Letters to the Editor.

The American Water-Works Association.

Sir:—Your account of the meeting of the American Water-Works Association was most gratifying. There are other members of the organization as well as myself who have no sympathy with much of the criticism passed upon it of late, yet are perfectly willing to acknowledge that in many respects the opportunities for its improvement are great. Inasmuch as you have treated the Association so fairly in your comments and have reported as successful a gathering that really was so, possibly you will allow me the privilege of making a few comments on its purposes, comments based on a knowledge of its history perhaps not possessed by some of its critics.

In the first place it must be distinctly understood that the American Water-Works Association is only indirectly an engineering organization. While most of its members are interested in the results of engineering practice, whenever they have important works to construct they retain the services of a professional expert. The members are mostly operating officials and the Association is intended to be for them what the American Street Railway Association is to the street railway superintendents. Purely engineering subjects, with but few exceptions, are better presented to the national engineering societies, where the technical details are understood by a larger proportion of the members. This is in no sense any criticism of the Water-Works Association; it is merely the statement of a fact, which has been so often overlooked that I am sometimes led to wonder what good the Association would be to most of its members were the suggestions of its critics carried out. The fact that papers on engineering subjects are rarely read at the conventions is more to be commended than deplored, and the absence of such papers, which some critics consider a sign of the Association's lack of utility, is an indication that it is confining its attention to its proper field.

The true criticisms of the Association are rarely made in print but it is time they were given general attention. The administrative problems of the superintendent of a water plant are fully as important as those of the electric light or the street railway manager, yet the great fault of the Association is its neglect of them. These problems will be much simplified by a free discussion of them, and the only way in which such a discussion can be held is to secure from each member a full statement of any difficulty that may arise in his work, for submission to the Association directly or through a committee. If an earnest endeavor is made to secure from all members such items of interest as occur to them in the next six or eight months, and these items are turned over to the publication committee for its consideration, the latter body can doubtless arrange for a series of papers and discussions at Detroit next summer which will surpass in interest and value anything accomplished in the past. To do this it is necessary to have the members frequently reminded of their duty to the Association, but with the present officials it goes without saying that any plan for the welfare of the organization that meets their approval will be pushed with the same energy that has won for them their position in the water-works fraternity. A Member.

New York, July 3.

Tunneling for Water at Los Angeles.

Sir:—A tunnel now in process of construction here is designed to cross the mouth of the San Fernando valley for the purpose of obtaining whatever waters may be passing through that neck by sub-flow in the gravel and sand detritus, which borings across the valley have demonstrated to have an average depth of 60 feet and a greatest depth of 95 feet. The watershed of the San Fernando valley and the mountain slopes tributary thereto have a combined area of about 480 square miles. In the present year the surface yield is 55½ cubic feet per second. This water is all diverted from the stream, which is known as the Los Angeles River, above the neck across which this tunnel is being driven, by various ditches, the main one of which supplies the domestic consumption of the city of Los Angeles.

The rock system at the neck consists of stratified argillaceous sandstone and shales which are soft enough to be easily tunneled and yet firm enough generally speaking to stand up without timbering. The detritus lying in the neck of the valley and from which we expect to develop the water is derived from crystalline rocks, mainly granitic, and yields water of very superior quality.

A shaft 12 feet in diameter has been sunk in the rock at one side of the valley to a depth sufficient to head a tunnel in the bed rock beneath the water-bearing gravels and sand in the valley. It is the purpose to perforate the casing of the wells which were originally driven to and below the bed rock to determine primarily the depth to bed rock, and permit the water to be drained into the tunnel, from which it can be pumped to a reservoir closely adjacent to the mouth of the shaft and distributed in the domestic mains of the water supply system.

The progress so far has been at the rate of about 6 feet in 24 hours in the tunnel which has now reached a distance of nearly 300 feet. No trouble so far has been experienced.

Yours truly, Wm. Mulholland,
Supt. Water Works.

Los Angeles, June 28.

A Boat's Motion in a Restricted Waterway.

Sir:—I regret to find on reading your observations on my letter published in the last (June 28) issue of The Record, that I failed to remove your misconception of the theory and the analysis based by Haak on his experiments on the Dortmund-Ems Canal. His hypothesis, as I have repeatedly stated, is not that the work represented by the negative velocity produced by a vessel moving in a narrow channel equals the entire resistance to the boat's motion, but that this negative velocity is a function of the whole resistance. He was aware that the energy represented by this velocity was but a fraction of the boat's resistance, and therefore sought an expression which should include all the complex elements of frictional resistance.

Such an expression necessarily includes the length of the boat as a factor, and required the elaborate system of measurements employed by him to record the position of the water surface the whole length of the boat, enabling him to determine the mean velocity and the weight of the mass of water, in which all the elements of resistance act, to which he applied the coefficient of all the resistances in his expression for the work.

Had he adopted the hypothesis you attribute to him, he would simply need to have measured the maximum depression of the water surface, instead of the mean depression the whole length of the boat, and the wet section of the boat in the vertical plane of this maximum depression instead of its mean wet section, thus determining the maximum negative velocity which is the only experimental element required by this hypothesis to determine the resistance of the boat.

If the notation of my paper be employed premising that ΔQ represents the maximum instead of the mean depression of the water surface and that q represents the wet section of the boat at the section of maximum depression instead of its mean section, the boat's resistance would be represented by the equation: $R = w\,(Q - \Delta Q - q)\,v^2 \div 2g$, affected only by the constant coefficient $1/2g$. That this is not an approximately true expression for canal resistance all experiments directed to its determination clearly demonstrate.

Truly yours, E. Sweet.

Albany, July 4.

[The Engineering Record regrets that Mr. Sweet cannot accept its analysis, which is based on the premises set forth by Haack and is the logical outcome of those premises. The formula for the resistance R, as given in its analysis, is correct as to form, but, as was stated, it needs the variable coefficient C to be determined by experiment.]

The Patrol System of Street Cleaning in use in Somerville, Mass., is briefly described in the 1901 report of Street Commissioner J. P. Prichard. The city is divided into districts, to each of which is assigned a man supplied with a hand cart and the necessary implements for removing waste paper and other rubbish, loose stones, etc. He is also required to fill depressions in the streets, replace loose bricks in sidewalks, and cut grass on borders of the walks.

Personal and Obituary Notes.

Mr. Robert Gray and Mr. Frank Collman have been elected city engineer and street and water commissioner, respectively, of Bristol, Va.

Mr. J. Hampden Dougherty has resigned as commissioner of water supply, gas and electricity of New York City, and Col. Robert Grier Monroe has succeeded him.

Mr. John Hays Hammond has accepted a professorship in the Sheffield Scientific School, of Yale University, to direct the practical part of the course in mining engineering.

Col. P. C. Hains, Lieut.-Col. Charles J. Allen and Maj. James B. Quinn, Corps of Engineers, U. S. A., have been appointed to superintend the improvement of the Norfolk, Va., harbor.

Capt. John S. Sewell, Corps of Engineers, U. S. A., has been appointed superintendent of the construction of the Army War College and auxiliary buildings at Washington Barracks.

James Stewart, head of the prominent contracting firm of James Stewart & Company, died July 5 in Pittsburg, in his eighty-first year, from the effects of an attack of pleurisy.

Mr. Burton J. Ashley, chief engineer in the founding of Zion City, Ill., a place of about 5,000 inhabitants, has moved his office from Chicago to the Administration Building of that city.

Col. H. M. Adams, Maj. George Derby and Capt. W. V. Judson, Corps of Engineers, U. S. A., have been appointed to prepare plans for the protection of the port of Galveston, Tex.

Harvey Farrington, Assoc. M. Am. Soc. C. E., has opened an office at 115 Broadway, New York City, for the general practice of engineering, making a specialty of water-front improvements, docks, foundations, masonry, etc.

Mr. J. W. Peterson, who was formerly connected with the Chicago sales department of the Stanley Electric Manufacturing Co., and the Northern Electrical Manufacturing Co., has been elected vice-president and general manager of the Electrical Equipment Co., 939 Monadnock Block, Chicago.

Mr. George T. Prince, M. Am. Soc. C. E., has been appointed first assistant engineer of the Bureau of Water Filtration, Philadelphia. He has been connected with the water-works of Boston, Oswego, Towanda, St. Paul, Atlantic City and Omaha, as well as engaged in railway and sewerage works, and some valves designed by him while engineer of the Omaha works were illustrated in this journal a few years ago.

William Fraser Garrison, of Guild & Garrison, pump manufacturers of Brooklyn, N. Y., died July 8, at his country home in Morristown, N. J., after a four months' illness. He was born about 69 years ago in Brooklyn, where he has since resided. He began his career as an apprentice and became successively journeyman, inventor and employer. At the time of his death he was a prominent factor in local industries.

The Engineering Department of the New York Central & Hudson River Railroad has appointed a number of inspectors to secure the observance of standard plans and specifications on work in progress and to assist in general supervision. Mr. W. A. Pettis has been appointed general inspector of buildings; Mr. J. H. Watson, general inspector of bridges; Mr. H. Latimer, general inspector of masonry work; Mr. A. M. Clough, general inspector of track; and Mr. C. A. Miller, general inspector of mechanical and electrical work.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

SUNDRY CIVIL APPROPRIATIONS.

Public Document No. 182, as passed by Congress, provides for the following additional appropriations for public buildings, etc.:

Alabama.—Montgomery, P. O. and Ct. H., $25,000.

Arkansas.—Fort Smith, P. O. and C. H., $25,000.

California.—Fresno, P. O. and C. H., $25,000; Los Angeles, Ct. H. and P. O., $200,000; San Francisco, C. H., $25,000.

Colorado.—Colorado Springs, P. O., $30,000.

Connecticut.—Hartford, P. O., Ct. H. and C. H., $50,000; Meriden, P. O., $45,000; Waterbury, P. O., $45,000.

District of Columbia.—National Bureau Standard Laboratory, $75,000; Treas., Butler & Winder Bldgs., $35,100; Bureau Eng. & Print., add. vaults, $50,000; heat. app., Pub. Bldgs., $150,000; vaults, safes and locks for Pub. Bldgs., $30,000; Municipal Bldg., $600,000.

Florida.—Pensacola, Quarantine Station, $30,000.

Georgia.—Atlanta, P. O. and C. H. and Ct. H., $170,000; Brunswick, C. H. and P. O., $50,000; Brunswick, P. O. and C. H. add., $30,000; Savannah, Marine Hospital, $50,000.

Idaho.—Boise, Pub. Bldg., $50,000.

Illinois.—Chicago, P. O. and C. H., $1,000,000; Joliet, P. O., $30,000; Springfield, P. O. & Ct. H., $25,000.

Indiana.—Indianapolis, P. O., Ct. H. and C. H., $100,000; Hammond, P. O. and Ct. H., $30,000.

Iowa.—Burlington, P. O., $25,000; Creston, P. O., $50,000; Des Moines, P. O., Ct. H. and C. H., $150,000; Waterloo, P. O. and Ct. H., $35,000.

Kentucky.—Paducah, P. O., Ct. H. and C. H., $25,000

Louisiana.—New Orleans, P. O., $200,000.

Maine.—Augusta, P. O., Ct. H. and C. H., $25,000.

Maryland.—Baltimore, C. H., $150,000; Cumberland, Ct. H. and P. O., $25,000.

Massachusetts.—Fitchburg, P. O., $25,000; Holyoke, P. O., $40,000.

Minnesota.—Fergus Falls, C. H. and P. O., $25,000; Minneapolis, P. O., Ct. H. and C. H., $25,000; St. Paul, C. H., $50,000.

Montana.—Helena, Pub. Bldg., $50,000.

Mississippi.—Biloxi, P. O. and C. H. and Ct. H., $25,000.

Missouri.—Joplin, P. O., $25,000; St. Louis, P. O., $210,000.

Nebraska.—Lincoln, P. O., Ct. H. and C. H., $25,000; Omaha, Ct. H., C. H. and P. O., $25,000.

New Hampshire.—Nashua, P. O., $25,000.

New Jersey.—Atlantic City, P. O., $30,000; Elizabeth, P. O., $60,000.

New York.—Buffalo, Marine Hospital, $60,000; Buffalo, P. O., C. H. and Ct. H., $35,000; Elmira, P. O. and C. H., $107,000; Jamestown, P. O., $40,000; Lockport, P. O., $25,000; New York, P. O., $25,000; New York, Marine Hospital, $250,000; New York, C. H., $150,000; New York, Ct. H. and P. O., $35,000; Niagara Falls, P. O., $25,000.

North Carolina.—Elizabeth City, C. H. and P. O., $50,000.

North Dakota.—Grand Forks, P. O. and Ct. H., $25,000.

Ohio.—Cleveland, P. O. and C. H. and Ct. H., $150,000; Toledo, P. O., $82,000; Zanesville, P. O., $25,000.

Oregon.—Portland, P. O. and C. H., $25,000.

Pennsylvania.—McKeesport, P. O., $25,000; New Castle, P. O., $25,000; Philadelphia, Mint, $25,000; Pittsburg, Marine Hospital, $60,000.

Rhode Island.—Providence, P. O., Ct. H. and C. H., $25,000.

So. Dakota.—Aberdeen, P. O., $56,500; Deadwood, P. O. and Ct. H., $30,000.

Tennessee.—Memphis, P. O., Ct. H. and C. H., $25,000; Nashville, P. O., Ct. H. and C. H., $25,000.

Texas.—Abilene, P. O. and C. H., $25,000; Dallas, P. O. and Ct. H., $25,000; Laredo, P. O., Ct. H. and C. H., $35,000; Sherman, P. O. and Ct. H., $30,000; Waco, P. O. and C. H., $25,000.

Utah.—Salt Lake City, Ct. H. and P. O., $50,000.

Vermont.—Burlington, P. O. and C. H., $25,000; Newport, Ct. H., P. O. and C. H., $50,000.

Virginia.—Newport News, P. O. and C. H., $50,000.

Washington.—Tacoma, P. O., Ct. H. and C. H., $100,000; Seattle, Ct. H., C. H. and P. O., $250,000; Spokane, P. O., Ct. H. and C. H., $100,000.

West Virginia.—Huntington, P. O. and Ct. H., $25,000; Wheeling, P. O., Ct. H. and C. H., $125,000.

Wisconsin.—Green Bay, P. O., $25,000; Janesville, P. O., $25,000; Superior, P. O., Ct. H. and C. H., $35,000.

Wyoming.—Cheyenne, Pub. Bldg., $74,983; Evanston, P. O. and C. H., $25,000; Laramie, P. O., $25,000.

Alaska.—Sitka, repairs, etc., Pub. Bldgs. and Wharf, $400,000; Light House and Fog Signal Stations in Alaskan waters, $126,013.

River and Harbor Work.

California.—San Pedro harbor, breakwater, $311,085.

Connecticut.—New Haven harbor, $67,000.

Dist. of Columbia.—Improv. Gray's Harbor, $156,775.

Florida.—Improv. Tampa Bay (from Gulf of Mexico to Port Tampa), $86,675.

Georgia.—Improv. Cumberland Sound (Ga. and Fla.), $400,000; improving Ocmulgee River, $56,000; improving Savannah River (between Augusta and Savannah), $86,000.

Illinois.—Calumet Harbor, $215,000; Ill. & Miss. Canal, $733,220.

Kentucky.—Improv. Kentucky River, $200,000.

Massachusetts.—Improv. Boston Harbor, $175,000.

Michigan.—Improv. Detroit River, $136,500; Hay Lake Channel, St. Mary's River, $144,115.

Minnesota.—Improv. harbor at Duluth (Minn. and Superior, Wis.), $459,727.

Mississippi.—Gulfport Harbor, $150,000; Mississippi River (from mouth of Ohio to Minneapolis, Minn.), $250,000.

New York.—Improv. harbor at Buffalo, $200,000; Gowanus Bay Channels, $100,000; N. Y. Harbor (Ambrose Channel), $150,000.

Ohio.—Improv. Ashtabula Harbor, $200,000; improving Cleveland Harbor, $107,000; Black River, $300,000; Toledo Harbor, $223,000.

Pennsylvania.—Locks and dams in Allegheny River (Herr Island), $118,500; Ohio River (below Pittsburg), dams Nos. 13 & 18, $46,600.

Rhode Island.—Improv. Providence River and Narragansett Bay, $84,560.

South Carolina.—Charleston Harbor, $50,000; Improving Congaree River, $50,000; Improving Winyaw Bay, $35,000.

Washington.—Everett Harbor, $117,000.

West Virginia.—Improv. Monongahela River (const. locks and dams), $350,000.

National Homes for Disabled Volunteer Soldiers.

Central Branch, Dayton, O.—Total appropriation $579,500, of which amount $56,500 is for repairs of roads and permanent improvement, and $6,000 for improving water supply.

North Western Branch, Milwaukee, Wis.—Total appropriation $316,625, of which amount $15,700 is for extension of electric light plant and $29,725 for repairs.

Eastern Branch at Togus, Me.—Total appropriation $335,275, of which amount $30,000 is for new barrack.

Southern Branch at Hampton, Va—Total appropriation $389,100, of which amount $28,050 is for repairs and $8,000 for water tube boilers.

Western Branch at Leavenworth, Kan.—Total appropriation $431,625, of which amount $11,500 is for extension of electric light plant, and $7,500 for extension of boiler house, and $6,500 for additional boilers, and $40,000 for one combination barrack, and $17,500 for headquarters bldg.

Pacific Branch at Santa Monica, Cal.—Total appropriation $324,150.

Marion Branch at Marion, Ind.—Total appropriation $347,150, of which amount $100,000 is for heating plant and $16,000 for combination barrack.

Danville Branch, Danville, Ill.—Total appropriation $306,700.

Mountain Branch at Johnson City, Tenn.—Total appropriation $3,723,969.

Miscellaneous.

Arkansas.—Hot Springs Reservation, protection and improv., $48,562.

California.—San Francisco Bay, Mile Rocks Light and Fog Signal Station, $100,000.

District of Columbia.—Bldg. to accommodate offices of President in grounds of Executive Mansion, including heating apparatus and light fixtures, $65,196; Government Hospital for Insane, general repairs and improvements $25,000, Administration Bldg. $145,000 central heating and lighting plant for entire Hospital, $260,000 (including $10,000 for sewers); Grant Memorial, $50,000; Nat. Zoological Park, improvement, $90,000; improving Potomac Park, $70,000.

Florida.—Hillsboro Inlet Light Station, $45,000.

Georgia.—Atlanta, for construction, residence of warden and deputy warden, and various other bldgs., $100,000; Sapels Light Station, light and keeper's dwelling, $40,000.

Kansas.—Fort Leavenworth, for continuing construction U. S. Penitentiary, $250,000.

Louisiana.—Government Bldg., La. Purchase Exposition (add.), $200,000.

Maine.—Portland Harbor, Ram Island Ledge Light and Fog Signal, $83,000.

Massachusetts.—Castle Island Lighthouse Depot, $25,000; Boston Harbor (Northeast Grave), Light and Fog Signal, $75,000.

New Jersey.—Port Penn Range, Reedy Island Range and Twins Point Range (Del. River), $30,000.

New York.—Staten Island Lighthouse Depot (oil house), $60,000.

Pennsylvania.—Phila., Schulykill Arsenal completion, add. to fireproof store house, clothing depot and installing elevators, $25,000.

Erection of barracks and quarters for artillery at military posts, $2,000,000.

Yellowstone Nat. Park, improvements, $250,000.

Chickamauga and Chattanooga Nat. Park, $50,000.

Shiloh National Military Park, $40,000.

Gettysburg National Park, $75,000.

Vicksburg National Military Park, $100,000.

WATER.

Whatcom, Wash.—It is stated that bids are wanted Aug. 3 for $60,000 bonds, the proceeds to be used to extend the water works. E. E. Hardin, Mayor.

Stoneboro, Pa.—Bids are wanted July 21 for constructing a water works system to consist of a 224,000-gal. concrete-lined reservoir, 12,000 ft. of 6-in. and 2,000 ft. of 4-in. cast pipe, standard weight, 10 hydrants, 75 taps with boxes, valves, etc. Frank McSweeney, Boro. Treas.

Beaumont, Tex.—Bids are wanted for constructing 25 miles of rice canal work from Pine Island bayou to Sour Lake, Tex. Address Brooks Bros. & Co., care Dutton Hotel, Beaumont.

San Diego, Cal.—City Engr. G. A. d'Hemecourt writes that the proposition to install additional auxiliary pumps for the purpose of pumping the water from San Diego River has been discussed by a Com. of the Common Council, but no definite report has as yet been made.

Ronceverte, W. Va.—Engr. in Charge F. R. Van Antwerp writes that bids will be received July 15 for 2 50-H. P. boilers, 2 pumps, 400,000-gal. capacity each per 24 hours; also pipe, hydrants, etc. John F. Weber, Town Recorder.

Centerville, Miss.—Town Clk. R. T. Quinn writes that on July 1 it was voted to issue $15,000 bonds for the construction of water works.

New London, Conn.—W. H. Richards, Engr. Water Dept., writes that a small high service water works system to include water power pump and small reservoir, the whole to cost about $25,000, is under consideration.

Shelby, O.—John B. Weddell, of Mansfield, O., has been engaged as Engr. in Charge of the construction of purification works for the Shelby Steel Tube plant, at Shelby.

Cleveland, O.—The lowest bid received July 2 by Chas. P. Salen, Dir. Pub. Wks., for building the superstructure of a boiler and cold storage house at Kirtland St. Pumping Station, also for a brick chimney at the same station, was from John Gill & Sons, of Cleveland, at $119,969.

Austin, Pa.—The time for receiving bids for the construction of water works has been extended from July 10 to July 17, as advertised in The Engineering Record.

Findlay, O.—City Engr. John W. S. Riegle writes that the City Council is about to receive bids for the sale of $150,000 water works improvement bonds. Contracts for work will also soon be let.

Consulting Engr. L. E. Chapin, of Canton, is stated to have approved the suggested project of using vitrified tile in bringing spring water to the city. The Water Works Bd. is about to engage an engineer to have charge of the water works construction.

Elkland, Pa.—Bids are wanted July 16 for a quantity of cast iron pipe, special castings, valves and fire hydrants, as advertised in The Engineering Record.

Hammonton, N. J.—Bids are wanted July 24 for furnishing all materials and plant for the laying of water pipe and appurtenances; separate bids are wanted until the same date for furnishing materials and erecting a steel standpipe, as advertised in The Engineering Record.

Mt. Gilead, O.—Bids are wanted July 23 for the construction of a complete water works system, Engr. John B. Weddell, of Mansfield, O., as advertised in The Engineering Record.

Boston, Mass.—Bids are wanted by the Metropolitan Water & Sewerage Bd. until July 25 for laying 2,600 lin. ft. of 60-in. cast iron water pipe in Weston and Newton, including the construction of a coffer dam, the laying of 3 lines of pipe each about 350 ft. in length under Charles River, and the placing of about 800 cu. yds. of concrete, as advertised in The Engineering Record.

Monticello, Minn.—Village Recorder W. J. Thompson writes that on July 29 a vote will be taken on the issue of $10,000 bonds for water works and $4,000 bonds for a gas plant.

Whitehouse, O.—S. B. Eipler, Clk. of Water Wks. Trus., writes that it is proposed to construct water works, at a probable cost of $7,000. Bids for bonds will be opened July 30, and after that bids for construction will be received.

Washington, D. C.—Col. A. M. Miller, in charge of the Washington aqueduct, has sent to the Ch. Engr. of the Army his project for the completion of the filtration plant, which contemplates a filter plant of 75,000,000-gal. daily capacity. Appropriation available, $600,000.

Caldwell, Idaho.—A press report states that bids are wanted July 24 for water works, according to plans of Engr. Cummings, which provide for wells at Frosts Springs.

Munhall, Pa.—The Council has passed an ordinance authorizing the issue of $70,000 bonds, of which amount $25,000 is for a water system and $20,000 for a municipal building.

Burlington, Ia.—Judge Withrow, of the Dist. Court of Des Moines County, has granted the application of W. W. Baldwin and others for an injunction to restrain the city of Burlington from entering into the contract with Hayes & Sons, of Cleveland, O., for the purchase of the water works.

Cornwall, Ont.—The Town Council has awarded the contract for the new hydraulic pumping plant to the Goulds Manufacturing Co., of New York and Boston, who agree to furnish a pump with a capacity of 1,500,000 gal. per day and a Jenckes water wheel set up for $7,490.

San Jose, Cal.—Local press reports state that plans prepared for the extension of the water system include the doubling of the pumping capacity and extension of pipe lines.

Youngstown, O.—Local press reports state that the Water Works Trus. propose to put in an experimental filter plant, to decide the question of whether or not Mahoning River water can be successfully filtered.

Belleville, Ill.—The plant of Mother Earth Water Co. is reported to have been destroyed by fire.

Birmingham, Ala.—The Birmingham & Suburban Water Works Co. has applied for a franchise in East Lake, Avondale, Woodlawn and West End.

Trenton, O.—C. D. Lewis, of Greenville, O., is stated to have submitted a report on the proposition to establish a water works system.

Lewisville, Idaho.—The Little Feeder Canal Co., Ltd., has filed its articles of incorporation. The incorporators are: S. G. Marier, Ed. Ellsworth, Sr., Erastus Walker and others.

Deerfield, Mass.—The voters of South Deerfield Fire Dist. have accepted the provisions of the recent legislative act enabling the district to take water from Whately Glen brook for domestic and fire purposes.

New Albany, Ind.—The City Council has granted the Indiana Water Co. the right to pump water from the river instead of from wells in the eastern part of the city.

Brooklyn, N. Y.—Asst. Ch. Engr. Van Buren is said to be preparing plans for a new 36-in. main, which it is proposed to lay on Atlantic Ave., between Carlton and Flatbush Ave.; probable cost about $60,000.

Oakland, Md.—Pres. L. A. Yoder, of the Mountain Lake Water Co., has submitted a proposition to establish water works in Oakland.

La Grande, Ore.—This city is said to be considering a proposition for the installation of a new water and electric light plant by Robt. Strathon, who proposes to purchase the present water system, to construct a sewerage system, to develop power for manufacturing and other purposes and to operate an electric light plant. Total estimated cost about $200,000.

Golden, Colo.—Local press reports state that this city proposes to construct a new gravity system of water works.

Belleville, Wis.—The proposition to issue water works bonds is reported to have carried.

Sacramento, Cal.—Mayor Clark has signed the contract with Geo. F. Day for a 2,000,000-gal. pump for the water works, at $1,600.

Buffalo, N. Y.—Local press reports state that Col. Francis G. Ward, Comr. of Pub. Wks., is in favor of a new and second pumping station.

Chariton, Ia.—The City Council has under consideration a proposition for the installation of a water works plant at a cost of $4,800.

Johnstown, O.—It is stated that bids are wanted Aug. 2 for $12,000 water bonds. H. B. Ruslin, Mayor.

Mitchell, S. D.—Bids are wanted July 17 for several blocks of water mains. W. M. Herbert, City Aud.

Whatcom, Wash.—It is stated that bids are wanted Aug. 18 for the purchase of $60,000 water bonds. W. H. Hildebrand, City Clk.

Oriskany Falls, N. Y.—The following bids are stated to have been received for the construction of a system of water works: Wm. T. O'Connor, of Syracuse, $19,700; John N. Siegrist, Utica, $19,600. All bids were rejected because of recent upward prices of cast iron pipe and inability to go beyond the amount voted for. Another supply at less cost is being examined into by F. K. Baxter, C. E., Utica, N. Y., and if possible the work may be let yet this season.

Charleston, S. C.—The stockholders of the Charleston Light & Water Co. are stated to have authorized an increase of the company's capital to $1,000,000, and authorized the issue of $1,500,000 bonds. A. H. S. Post, of Baltimore, Pres., and Morris Israel, Vice-Pres. The contract for constructing the water works plant has been let by the Charleston L. & W. Co., to the American Pipe Mfg. Co., and it is stated that work will be started at once.

Artesian, S. D.—Press reports state that bids are wanted July 21 for sinking an artesian well.

Edgerton, Minn.—Village Recorder C. I. Ring writes that the contract for constructing water works has been awarded to W. D. Lovell, of Des Moines, Ia., for $6,043.

Gueydan, La.—J. G. Neelis, Secy. & Treas. of the Gueydan Water & Power Co., recently incorporated, with a capital of $15,000, writes that the company proposes to put in a system of water works, manufacture ice, light, etc.

Carthage, Mo.—J. T. Lynn, of the James T. Lynn Water Co., writes that his company, which recently secured control of the plant of the Carthage Water Co., proposes to improve said plant at a probable cost of $50,000, including filter. G. G. Bayne, of Joplin, Mo., Engr. in Charge.

Brooklyn, N. Y.—Bids will be received by J. H. Dougherty, Comr. Dept. of Water Supply, Gas & Electricity, Room 1536, Park Row Bldg., N. Y. City, until July 24, for furnishing, constructing and erecting a pumping plant, with all appliances complete, at the Milburn Engine House, Baldwins, L. I.

Bridgeburg, Ont.—Bids are wanted July 21 for $32,000 water bonds. H. Emrick, Village Clk.

Lancaster, Ky.—The Artesian Well Supply Co., of Providence, R. I., has received the contract for drilling a well for the town supply.

Chinook, Mont.—City Clk. M. F. Marsh writes that it is proposed to construct water works at an estimated cost of $24,000 to $26,000. Wolf & Roth, of Minneapolis, Minn., are to prepare estimates, and bonds will be voted July 26.

Portsmouth, N. H.—The Water Comrs. recommend the issue of $50,000 for the acquirement of Peverley Brook in Newington for an increased water supply.

St. Ansgar, Ia.—The Com. on Water Works is stated to have received plans and specifications for a new system from the Des Moines Bridge & Iron Co.

Columbus, O.—The State Bd. of Health is reported to have approved the revised plans for a 30-ft. dam in Scioto River, with the proviso that he water so stored be purified before being used by this city.

Pony, Mont.—In a report to the City Council as to the best system of water works for this place, Harper & McDonald, of Butte, recommended that a reservoir be built for the storage of spring water; estimated cost, $14,326.

Yonkers, N. Y.—The Bd. of Water Comrs. has voted to have John A. Byrne and W. F. Washington, of the Hydraulic Const. Co., which has the contract for lowering the suctions at the tube well plant, and Wm. H. Baldwin, Engr. to the Bd., each present a separate report, with plans, for filter beds at the tube well plant. In reports already submitted Mr. Byrne and Mr. Washington favor the natural sand filtration system, and Mr. Baldwin favors the mechanical system of filtration, and he estimates the total cost of such a plant at $66,000.

A. W. Kingsbury, Clk. Bd. of Water Comrs., writes that the following bids were opened July 9 for furnishing and delivering 425 lengths of 12-in. pipe, 1,060 lbs. per length of 12 ft.; prices are per ton: U. S. Cast Iron Pipe & Fdy. Co., Philadelphia, Pa., $32.90; Chas. Millar & Son Co., Utica, N. Y., $34.08; R. D. Wood & Co., Philadelphia, Pa., $31.45; M. J. Drummond & Co., New York City, $33; Wm. Y. Briggs, New York City, $37; John Fox & Co., New York City, $33.55; Warren Foundry & Machine Co., New York City, $31 (awarded); Camden Iron Wks., Camden, N. J., $31.45.

SEWERAGE AND SEWAGE DISPOSAL.

Bronxville, N. Y.—The time for receiving bids for sewerage and septic tank has been postponed from July 15 to July 21, as advertised in The Engineering Record.

Redfield, S. D.—Bids are wanted July 21 for constructing sewers in several streets. J. S. Huston, City Aud.

Youngstown, O.—Bids will be received by the City Comrs. until July 19 for grading, draing and improving Forest Ave. and constructing sewers in Himrod and Foster Sts. C. E. Cross, Clk.

Des Moines, Ia.—Bids are wanted July 23 for a 12-in. vitrified clay pipe sewer on E. 13th St. and a 15-in. vitrified clay pipe sewer on E. Washington St.; also on July 24 for a 12-in. vitrified clay pipe sewer in portions of 16 streets. J. E. Stout, Chmn. Bd. Pub. Wks.

Carthage, N. Y.—Plans prepared by Brownell & Eaton for the West Carthage sewer system are stated have been submitted to the State Bd. of Health for approval.

Columbia, Mo.—The City Council will receive bids until July 22 for furnishing labor and material necessary to construct sewers in Dists. Nos. 9 and 10. John S. Bicknell, City Clk.; E. B. Cauthorn, Engr. Probable cost, $4,000.

Wilmington, Del.—Ch. Engr. J. A. Bond, of the Water Bd., writes that the contract for constructing a concrete sewer (about 700 ft. long) in Brandywine Park, has been awarded to Harry A. Miller, 617 Shipley St., Wilmington, at $5.66 per lin. ft.

Meadville, Pa.—City Engr. W. A. Doane writes that resolutions have been passed for the construction of sanitary 8-in. sewers on Mercer and West Sts. Cost about $10,000.

Derby, Conn.—City Clk. John W. Larkin writes that bids received July 2 for sewer construction have been rejected and that the city will do the work under the supervision of the Comr. of Streets, Jas. J. Sweeney.

Mt. Gilead, O.—John B. Weddell, of Mansfield, O., has been employed as Engr. in Charge of the construction of a sewer system and purification works for this place.

Kendallville, Ind.—Bids are wanted July 15 for the construction of a sewer on Oak St. E. P. Lash, City Clk.

Canton, O.—Bids will be received July 21 for the following quantities of "first quality" salt-glazed vitrified shale sewer pipe, f. o. b. Canton, breakage and inspection guaranteed: 7,500 ft. 18-in. double strength, 2,000 ft. 15-in. d. s., 800 ft. 12-in. standard strength, 6,000 ft. 10-in. s. s., 45,000 ft. 8-in. s. s., and 8,500 ft. 6-in. s. s., with necessary branches.

Bids are wanted Aug. 4 for constructing sanitary sewers in Dist. No. 1, said work, 15 miles in all, to be let in 3 sections. Blank forms of bids will be furnished by the City Engr. Plans and specifications are on file at the office of City Engr. Phil. H. Weber.

Quincy, Mass.—The City Council on June 30 appropriated $60,000 for sewer extensions. H. Flood, City Engr.

Monticello, Ind.—City Clk. W. J. Gridley writes that bids received June 30 for constructing sewers Nos. 8, 9 and 10 were rejected and new bids will be opened July 25.

White Plains, N. Y.—Bids are wanted by the Village Bd. of Trus. until July 22 for building an engine and pump house, building pump well or suction chamber, furnishing and setting two 20-H.-P. gasoline engines, 2 triplex power pumps of 500 gals. per minute capacity combined, together with all necessary pipes and fittings to connect and operate a sewage pumping station with present system of sewers. Peter Paulding, Village Clk.

Lockhart, Tex.—Bids will be received until about July 23 for constructing a sewer system. Address the Mayor.

Gainesville, Ga.—It is stated that bids are wanted July 18 for $20,000 sewer bonds.

Cincinnati, O.—Bids are wanted Aug. 2 by the Hamilton Co. Comrs. for constructing a concrete semi-circular arch culvert in Ross Run Creek on Carthage Pike; also for constructing a concrete semi-circular arch culvert in Bloody Run Creek, on Carthage Pike. Eugene L. Lewis, Co. Aud.

New York, N. Y.—Bids are wanted July 18 for the following sewer construction: In 157th St., 222 ft. 15-in. salt-glazed vit. stoneware pipe, 50 cu. yds. of rock excavation, etc. In W. 186th St., 180 ft. 15-in. salt glazed vit. stoneware pipe, 425 cu. yds. of rock excavation, etc. In Wicker Pl., 215 ft. brick sewer 3 ft. 6-in.x2 ft. 4-in., 1,260 ft. 15-in. stoneware pipe, 1,925 cu. yds. rock excavation; also for 12 receiving basins. Jacob A. Cantor, Pres. Boro of Manhattan.

Mansfield, O.—Bids are wanted July 18 for the construction of 2 sanitary and 1 storm water sewers. D. S. Koontz, City Clk.

De Pere, Wis.—Bids are wanted by the City Clk. until July 26 for the construction of 3 sewers, 20 to 12 ins. in diameter. John Cook, Chmn. Com. on Sewers.

East Liverpool, O.—Bids are wanted July 15 for the construction of 6-in. sewers on Ravine St. and Thompson Ave. F. H. Croxall, Secy. Bd. of Sewer Comrs.

Cleveland, O.—Bids are wanted July 15 for the construction of sewers in Clement, Crane, Ditton and several other streets; bids are also wanted until July 22 for the construction of sewers in Detroit and Prescott Sts. Chas. P. Salen, Dir. of Pub. Wks.

Olathe, Kan.—Bids are wanted July 15 for constructing lateral sewers, about 1,000 ft. of 8-in. pipe, with Y connections, etc. S. F. Garwood, City Clk.

Zanesville, O.—Bids are wanted July 19 for a sewer in Pierce St., and until July 26 for a sewer on Harrison St. C. W. McShane, City Clk.

Fayette, O.—Bids are wanted July 21 for constructing a 5-in. sewer commencing at the creek on N. Fayette St. and running to Fayette and Union Sts. Fred. L. Bird, Village Clk.

Long Island City, L. I., N. Y.—Bids will be received by Jos. Cassidy, Boro. Pres., until July 24 for furnishing labor and material for constructing sewers in portions of 5 streets.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until July 21 for constructing sewers and drains in Slack St. and Beresford and James Aves.; also on Aug. 4 for constructing sewers and drains in numerous streets. Geo. F. Holmes, Clk.

Jeffersonville, Ind.—Bids are wanted Aug. 5 for a sewer 804 ft. long, 24-in. tile pipe double strength, with 3 manholes and 4 catchbasins; average cut 6 ft. Victor W. Lyon, City Engr.

Abilene, Kan.—Bids are wanted Aug. 6 for the construction of a system of public and district sewers, as advertised in The Engineering Record.

Norristown, Pa.—Bids are wanted July 14 for the construction of storm sewers in several streets. John H. Rex, Chmn. Sewer Com.

Cincinnati, O.—The Bd. of Pub. Service has approved specifications for an $11,000 trunk sewer to be built in the ravine west of Torrence Road.

Wellsville, O.—H. E. Riggs, of Riggs & Sherman, Toledo, is stated to have been employed as Consulting Engr. for the proposed sewerage system.

Atkin, Minn.—Geo. Ralph is said to be making surveys for the 40 miles of ditches to be constructed this year in Aitkin Co. by the order of the State Drainage Comn., Minneapolis.

San Diego, Cal.—The City Engr. has prepared estimates and plans for sewer extensions under the proposed bond issue for the part of the city south of N St. and west of Chollas valley; the total length of 6 to 20-in. vit. pipe is given as 70,647 ft., with 28 flush tanks, and 212 manholes; estimated cost, $67,-081. For the extension in the northern part of the city the estimate calls for 54,956 ft. of 6 to 12-in. vit. pipe, with 25 flush tanks, and 144 manholes; estimated cost, $69,012.

Oneida, N. Y.—See "Paving and Roadmaking."

West Hazleton, Pa.—The lowest bids received for the construction of a sewer system are stated to have been from Ludwig Kramer at $7,819 for the stone arch sewer and from Chas. Kehoe at $8,446, $3,[illegible] and $5,433 respectively for Sections 3, 4 and 5.

Hicksville, O.—The Council has adopted a resolution providing for the construction of a sewer from the n. w. side of town to the east side, 5,700 ft.

Manchester, Conn.—The Directors of the Manchester Sanitary & Sewer Dist. are considering a plan for sewers for the North End. Estimated cost, [illegible].

Grafton, N. D.—A vote was taken at the recent election in favor of drainage and paving.

Independence, Mo.—See "Paving and Roadmaking."

St. Paul, Minn.—Bids are wanted July 17 for constructing sewers in Cook and Bellows Sts. R. L. Gorman, Clk. Bd. Pub. Wks.

Ardmore, Pa.—It is stated that bids are wanted Aug. 4 for constructing 41 miles of pipe sewers, sewage disposal and pumping plant, etc. W. E. Barrett, Chamn. Com. Chester E. Albright, Engr., Land Title Bldg., Philadelphia.

Grafton, N. D.—Bids are wanted July 26 for the construction of a sewerage system, consisting of 3,202 ft. of main sewer, 12,243 ft. of laterals, 35 manholes and 87 catch basins. Benj. A. Provoost, City Aud.

Schenectady, N. Y.—Local press reports state that bids are wanted July 15 for constructing a 28-in. sewer in Nott St. and also on same date for paving the street.

Waterbury, Conn.—Bids are wanted July 15 for the construction of storm water conduits in 3 streets. R. A. Cairns, City Engr.

Kansas City, Mo.—Bids are wanted July 16 for constructing sewers in Sewer District No. 148. Robt. W. Waddell, City Engr.

Carbondale, Ill.—Bids are wanted July 21 for constructing a sewerage system. Sewer 6,500 ft. long, 8, 10 and 12-in. pipes, 6 manholes, flush tank, etc. F. M. Caldwell, City Clk.

Westfield, Mass.—It is reported that bids are wanted about July 19 for the construction of a sewerage system; appropriation $105,000. O. E. Parks, Town Engr.

Syracuse, N. Y.—Bids are wanted July 14 for furnishing materials and constructing an 18-in. pipe sewer in Fulton St. Geo. J. Metz, City Clk.

Cincinnati, O.—The City Engr. estimates the cost of constructing a sewer in Considine, Murdock and Hawthorne Aves. at $14,583; he states that if this sewer is constructed it will be necessary to also construct sewers in Bassett and Grand Aves., making the total cost $31,000.

Morgantown, W. Va.—Sewer and paving bonds to the amount of $30,000 have been sold by this city.

Camden, N. J.—The Street Com. has instructed City Engr. Farnham to prepare plans for sewers for the Line Ditch meadows. It is stated that the cost of said sewers may be $75,000.

Newark, N. J.—The following bids were opened June 26 for building Section 4, 2d and 3d Division, of the West Branch of the Joint Outlet Sewer. Alexander Potter, 150 Nassau St., New York City, Ch. Engr.:

Items and Quantities.	Earl & Dougherty, Jersey City.	David Peoples, Phila.	Harrison Cons. Co., Newark.	Batt & Martin, S. Orange.	Wm. Hanna, Newark.
24-in. pipe sewer:					
0—6 ft. deep, 3,215 ft.	$2.40	$2.60	$2.10	$2.43	$2.75

Lima, O.—The City Council has sold sewer bonds to the amount of $50,000.

Saranac Lake, N. Y.—Village Clk. S. A. Miller writes that the following bids were opened July 8 for constructing approximately 43,405 ft. of 6-in. to 24-in. pipe sewers, with 130 manholes and 12 flush tanks; the trench to average 10 ft. in depth and be excavated in sand, loam and rock: Fitzpatrick & Costello, Plattsburg, N. Y., $52,455 (awarded); Albert M. Banker, Gloversville, N. Y., $64,871; B. Gaffney & Sons, Saratoga Springs, N. Y., $63,619; W. H. Cooke, Niagara Falls, N. Y., $55,750.

San Juan, P. R.—City Engr. I. A. Canals writes that the following bids, which were opened June 20, were both rejected by the Municipal Council: Bidders: A, Larrinaga & Co., 27 William St., New York City; B, Sucesores A. Mayol & Co., Allen St., San Juan: 2,800 ft. 8-in. vit. salt-glazed sewer pipe, A, 26½ cts.; B, 27¾ cts. 4,800 ft. 10-in. vit. salt-glazed sewer pipe A, 40 cts.; B, 43 cts. 1,300 ft. 12-inch vit. salt-glazed sewer pipe, A, 51 cts.; B, 57 cts. 100 Y pieces, 8 in.x6 in., A, 94 cts. each; B, $1.26. 200 Ys, 10 in.x6 in., A, $1.40; B, $1.69. 50 Ys, 12x6, A, $1.85; B, $2.50.

Eureka, Cal.—City Engr. Frank E. Herrick writes that bids were opened June 20 for the construction of a sewerage system, the work to include 57,000 ft. of 6 to 24-in. pipe sewers, 2,655 ft. of outfall sewer, sectional area 36-in. in diameter, wood stave pipe; 116 manholes, and 71 lamp holes; the trench to average 6½ ft. in depth and be excavated partly in sand with some water, and partly in clay and compact sand. The contracts have been awarded as follows: To Wm. Heafey, of Oakland, sections 2, 3, 4 and 5, at $23,525, $33,182, $5,360 and $5,950, respectively; to J. Simpson, of Eureka, sections 1 and storm sewers, for $14,532. Total, $82,549.

Brockport, N. Y.—Village Clk. H. E. McArthur writes that the following bids were opened July 3 for the construction of a sewerage system, the work to include $12^2/_3$ miles of pipe sewers 4 to 18-in. in diameter, 123 manholes and 52 flush tanks; also about 1 mile of storm sewers and disposal works: Casey & Murray, Rochester, N. Y., $63,403.36; E. H. Denniston & Co., Syracuse, N. Y., $64,825; Holahan & Kearns, Rochester, N. Y., $65,695.61; W. W. Read & Co., Niagara Falls, N. Y., $68,600; W. H. Cookman, Niagara Falls, N. Y., $69,525; Miller & Franklin, Niagara Falls, N. Y., $73,150.

BRIDGES.

Marinette, Wis.—The Counties of Marinette, Wis., and Dickinson, Mich., are asking for plans and specifications for an iron bridge to be built across Menominee River at Niagara. Appropriation, $16,000. Address J. B. Woods, Amberg, Wis.

Highshoals, Ga.—C. M. Harrison, Clk. Bd. of Comrs. & Revenues, Walton Co., Monroe, Ga., writes that the contract for constructing a 375-ft. steel highway bridge at Highshoals has been awarded to the Virginia Bridge & Iron Co., Roanoke, Va., for $4,995. The contract for the stone work was let separately to C. M. Howlson.

San Antonio, Tex.—See "Paving and Roadmaking."

Monticello, Ill.—Contracts will be let July 22 for an 80-ft. and a 60-ft. highway bridge on stone masonry. Plans and specifications may be had of Ira O. Baker, Engr., Champaign, Ill., or of the Town Clerks in Monticello and De Land.

Columbus, O.—Co. Surveyor Henry Maetzel writes that he is preparing plans for 2 bridges to cross the railroad tracks on Cleveland Ave. Contracts will be let after Aug. 1.

Camden, N. J.—A new bridge and 400-ft. approaches will probably be built to avoid grade crossing at Phila. & Atlantic City R. R. at Broadway.

Vicksburg, Miss.—See "Government Work."

San Saba, Tex.—Co. Clk. L. W. Rector writes that the contract for constructing a bridge between San Saba and Burmwood has been awarded to the Midland Bridge Co., of Kansas City, Mo., for $8,300 (bids opened June 30).

Walker, Minn.—See "Paving and Roadmaking."

Mauston, Wis.—Bids are wanted Aug. 1 for the construction of a single span steel bridge across Lemonweir River on Union St.; it will be 140 ft. long, with 16-ft. roadway and 6-ft. sidewalk. R. S. Joslin, City Clk.

Tupperville, Ont.—Bids are wanted July 26 for the construction of a steel drawbridge across Sydenham River in this village. Address Archie McArthur, Municipal Clk. Twp. of Chatham, Tupperville.

Tipton, Ind.—Bids are wanted by the Bd. of Comrs., Tipton Co., until July 26 for building 10 small steel bridges and 2 small stone arch bridges. E. Perry, Co. Aud.

Wilkesbarre, Pa.—Bids are wanted July 26 for building numerous small bridges, mostly stone, in Luzerne Co. Geo. R. McLean, Co. Compt.

Mansfield, O.—Bids are wanted July 18 for constructing a bridge across Touby's Run, and for constructing 2 arches across Ritters Run. D. S. Koontz, City Clk.

Boston, Mass.—Bids are wanted July 17 for building 2 masonry abutments for Cambridge bridge. Patrick A. Collins, Chmn. Cambridge Bridge Com., Boston.

Cambridge, Mass.—It is stated that an order was voted by City Council for a loan of $100,000 for the new Cambridge bridge.

Chillicothe, O.—Bids are wanted July 21 for furnishing all material and constructing the substructure for a bridge to be built over Walnut Creek on the Mooresville and Londonderry road; bids will also be received at the same time for building the superstructure of said bridge, which is to have 1 span 64 ft. out to out. Harry S. Adams, Aud., Ross County.

Chicago, Ill.—Bids are wanted Sept. 3 for constructing the substructure of 18th and Loomis St. bridges across Chicago River, both bridges to be of the Scherzer rolling lift design. Thos. A. Smyth, Pres. Bd. of Trus., Sanitary Dist. of Chicago.

New Bedford, Mass.—It is reported that the Common Council has adopted an order for a special appropriation of $25,000 for the approach to the park bridge.

Sioux City, Ia.—Press reports state that City Engr. Lewis has recommended the construction at once of an 800-ft. viaduct on Wall St. from Fourth to Grand Sts. Probable cost, $100,000, to be borne by Ry. Co.

Kankakee, Ill.—The 187-ft. steel wagon bridge over the Iroquois River at Sugar Island is reported washed away. Cost, $11,000.

Waterloo, Ia.—The Black Hawk Co. Supervisors are reported to have estimated loss by recent high water as $20,000, 20 bridges having been washed away.

Toledo, Ia.—It is stated that $20,000 is needed to replace and repair bridges wrecked in Tama Co.

Sand Point, Idaho.—Local press reports state that contracts have been awarded to Geo. S. Deeks & Co., of St. Paul, for the construction of 46 piers for the steel R. R. bridge across Lake Pend d'Oreille, to replace wooden trestle bridge.

Zeeland, Mich.—Press reports state that the Grand Rapids Bridge Co. was awarded the contract for concrete arch bridge over Black River.

Cambridge, O.—Press reports state that the Pennsylvania R. R. bridge north of here has been washed from its abutments. Several street bridges are also reported washed away.

Zanesville, O.—It is reported that over 50 Co. bridges, ranging in length from 10 to 100 ft., have been destroyed by storm.

St. Paul, Minn.—Press reports state that action is to be taken to compel the Chicago Great Western R. R. to replace the State St. bridge over the tracks by a steel structure.

Wakefield, Can.—It is reported that at a recent vote of the township it was decided to build a bridge over the Gatineau River just above Wakefield.

North Yakima, Wash.—It is reported that ¼ of the $30,000 required to be raised by citizens to secure terminal grounds for the Yakima-Sunnyside R. R. and to build a bridge across Yakima River has been raised.

Bay City, Tex.—Matagorda Co. is reported to have sold $23,000 bridge bonds.

Stewartville, N. J.—Press reports state that the Bd. of Freeholders has voted to issue $25,000 in bonds to replace bridges destroyed by flood.

Ballard, Wash.—It is stated that F. Berzoue has applied to the Council for a franchise to build a drawbridge across Salmon Bay, the trestle to extend from Shilshole Ave. in Ballard west along Second Ave., and would connect with 23d Ave. in Seattle.

Grassport, Pa.—Press reports state that a charter has been granted to the West Elizabeth & Dravosburg Bridge Co., which will commence the erection of a bridge across the Monongahela River. W. T. Pierce, McKeesport, Pres.

Toronto, Can.—Press reports state that the Glen Road bridge near Rosedale is to be thoroughly strengthened.

Danville, Ill.—Bids are wanted July 17 for the construction of a steel bridge across the Vermillion River in Ellsworth Park. R. E. Lloyd, City Clk.

St. Louis, Mo.—Bids will be received by the Bd. Pub. Improv. until July 29 for the construction of a storage coal shed and steel railroad bridge over conduit at Bissels Point. Hiram Phillips, Pres.

Le Roy, N. Y.—It is reported that the Highway Comrs. are in favor of having the town co-operate with the Buffalo & Depew Ry. Co. in building a bridge over the Oatka River at Main St.

Como, Mont.—Press reports state that the Ravalli Co. Clk., Hamilton, Mont., will soon let the contract for rebuilding Como bridge.

Orange City, Ia.—Press reports state that a steel bridge will be erected over Rock River, 2½ miles from Rock Valley.

Hondo, Tex.—It is reported that the Comrs. have authorized the issue of $30,000 bonds for bridge purposes.

Cincinnati, O.—The Bd. of Pub. Service has been petitioned to issue $200,000 in bonds to build a viaduct connecting the end of Grandin road with Delta Ave.

Joliet, Ill.—It is stated that $12,000 will be needed to repair the Red Mill wagon bridge over Hickory Creek.

Rockwood, Tenn.—It is stated that the Tennessee Central R. R. has decided to put a 3-span steel bridge over the Cumberland River 300 ft. below the Hyde's Ferry bridge. Estimated cost, $150,000. J. E. Rodes, Gen. Mgr., Rockwood, Tenn.

Buffalo, N. Y.—Bids are wanted July 22 for the construction of the substructure and approaches for a bascule bridge on S. Michigan St., as advertised in The Engineering Record.

Rome, N. Y.—The contract for constructing a bridge over Mohawk River at E. Dominick St. has been awarded to Owego Bridge Co., Owego, N. Y., for $14,-500.

Buffalo, N. Y.—Bids are wanted July 22 for the superstructure of a bridge on South Park Ave. over Cazenovia Creek. Francis G. Ward, Com. of Pub. Wks.

Washington, Pa.—Press reports state that E. Jay Iams, Lee Grimes and Jesse Gibson have been appointed viewers to pass on the advisability of erecting a new county bridge over Pike Run Creek in West Pike Run Township.

Coldwell, Idaho.—It is stated that bids are wanted Sept. 9 for the construction of a bridge across Fayette River, to be 352 ft. long, 16 ft. wide, of 2 spans, with steel tubular piers. J. N. Bernard, Chmn. Bd. Co. Comrs.

PAVING AND ROADMAKING.

Red Bank, N. J.—The contract for building the Red Bank and Oceanic stone road has been awarded to the Rocky Hill Construction Co. at 72 cts. per sq. yd.; total, $21,560.

Jersey City, N. J.—The Freeholders of Hudson Co. have sold $65,000 bonds, the proceeds of which are to be used in the improvement of Paterson plank road from Monroe St., Hoboken, to Leonard St., Jersey City Heights.

Monroe has reported, recommending the following appropriations: Building construction, $936,000; roads, walks and grounds, exterior to the post, $50,000; sea wall and grading along Hygeia Hotel site, $25,000; sea wall and grading west of Sherwood Hotel, $20,000; total, $1,031,000.

Winthrop, Mass.—Bids are wanted Aug. 7 for erecting a brick hospital at Ft. Banks, Winthrop. A. W. Chase, Q. M.

Denver, Colo.—The following bids were opened July 7 at the Treasury Dept., Washington, D. C., for the mechanical equipment (except engines and generators), including plumbing, water supply, steam power plant, etc., heating apparatus, mechanical ventilation, electric wiring and conduits, switchboards, elevators and non-conducting covering for the U. S. Mint at Denver: *a*, atmospheric; *b*, vacuum: Allen Black, St. Paul, *b* $174,000; S. Faith & Co., Philadelphia, *a* $127,300, *b* $126,900; J. F. Buchanen & Co., Philadelphia, *a* $128,850, *b* $128,450; Thomas & Smith, Chicago, *a* $166,053, *b* $168,769; The Chris. Irving Co., Denver, *a* $153,626, *b* $156,883; H. B. Crain, Cincinnati, *a* $164,929, *b* $166,929; C. B. Kruse Htg. Co., Milwaukee, *a* $137,426, *b* $138,200; The Michael Htg. Co., Denver, *a* $197,027, *b* $200,874; Jos. M. Williams Co., Louisville, *a* $147,498, *b* $147,278.

Washington Barracks, D. C.—The Washington "Star" states that Capt. John S. Sewell, Corps of Engrs., has been assigned to the duty of superintending the construction of the Army War College and auxiliary buildings at Washington barracks. About $1,125,000 has been appropriated for the improvement of the military reservation known as Washington barracks, and of this sum about $400,000 is to be utilized in the construction of the War College building.

Chicago, Ill.—The following bids were opened on June 23 by Maj. J. H. Willard, Corps of Engrs., U. S. A., for constructing 2 miles of trunk, western section, Illinois & Mississippi Canal:

Bidders.	Mile 58, 86,337 cu. yds. Cts.	Mile 59, 112,104 cu. yds. Cts.	Total.
Callahan Bros. & Katz, Omaha	9.99	11.61	$21,640
Flynn Bros., Annawan, Ill....	11.4	24	36,747
Cogan & Pound, Chicago.....	14	22	36,750
John J. McCaughey, Chicago..	12.79	16.78	29,854

Amount available for this work, $25,000.

MISCELLANEOUS.

New York, N. Y.—Mayor Low has approved the ordinances providing for a $1,000,000 bond issue for the water grant improvements in charge of the Dock Dept.

Boston, Mass.—The following bids were opened July 3 by the Bd. of Harbor & Land Comrs. for dredging about 61,000 cu. yds. of material from the Commonwealth Flats at South Boston and dumping same at sea; prices are per cu. yd., measured in scows: Eastern Dredging Co., 22½ cts.; Emory R. Seward, N. Y. City, 23 cts.; Bay State Dredging Co., Boston, 20½ cts.; Morris & Cummings Dredging Co., N. Y. City, 17.4 cts.; J. S. Packard Dredging Co., 425 Angell St., Providence, R. I., 14⅞ cts. (awarded).

Buffalo, N. Y.—Bids are wanted July 19 for $100,000 abatement nuisance of Ohio Basin Slip bonds. F. W. M. Heerwagen, Compt.

Portland, Ore.—Bids are wanted July 25 (readvertisement) for a floating wooden drydock in 5 sections, according to plans of Jas. E. Blackwell, Dexter Horton Bldg., Seattle, Wash. E. T. C. Stevens, Clk. Bd. Port of Portland Comn.

Lebanon, Pa.—The City Engr. has made estimates for both a concrete and a rubble masonry channel around the southwestern part of the city, for the purpose of remedying the floods that have from time to time done much damage. The work will involve the expenditure of some $40,000. Abram Hess, Mayor; I. L. Beckley, City Clk.

Port Hawkesbury, N. S.—Bids are wanted at the office of the Dept. of Pub. Wks., Ottawa, Ont., until July 19, for the reconstruction and extension of the "Long Wharf" at Port Hawkesbury. C. E. W. Dodwell, Res. Engr., Halifax, N. S.

Boston, Mass.—Bids are wanted July 31 for building a stone breakwater at entrance to Apponagansett Harbor, Buzzards Bay, as advertised in The Engineering Record.

New York, N. Y.—The following bids were opened July 8 at the office of the Dept. of Docks & Ferries, for furnishing and delivering, Class I, 7,000 bbls. of slow setting, and Class II, 3,000 bbls. of quick setting Portland cement; prices are per bbl. and the same for both classes of cement: John P. Kane Co., 287 4th Ave. (awarded), at $1.72; John E. Sparrow, 15 Whitehall St., at $2.23.

Baltimore, Md.—The Baltimore & Ohio R. R. Co. is stated to have accepted plans for an iron pier at Locust Point to cost $600,000. The new structure will be 800 ft. long, 50 ft. high, 160 ft. wide, and have two decks, upon each of which tracks will be laid.

NEW INDUSTRIAL PLANTS.

P. A. Chum & Co., Rochester, N. Y., have let a contract for a brass foundry and machine shop, to be about 100x329 ft., and will install a 100-H.-P. engine, a boiler and probably a crane.

The North Dakota Mill & Grain Co., Courtenay, N. D., will rebuild its mill, recently burned. The mill will have a capacity of 100 bbls., grain storage of 25,000 bu. and will be of fireproof construction. The steam plant was not damaged, and it is probable that electric motors will be installed.

The Oelwein, Ia., Foundry & Machine Co. will have a 156x92-ft. iron and brass foundry. The power will be partly electric and partly steam. The former will be purchased, and the latter will require a boiler of about 40 H.-P. and an engine of about 25 H.-P.

The American Knit Goods Mfg. Co., Wythe Ave. & Penn St., Brooklyn, N. Y., is erecting an additional mill of 7 stories and 100x125 ft. Electricity will be used for power.

The Farmers' Grain Association, York, Neb., wants bids for a 10,000-bu. elevator, to be run by a 10-H.-P. gasoline engine.

The National Rolling Mill Co., Hartford City, Ind., is putting in a scrap and a puddle furnace, extending its building, which is 70 ft. wide, about 30 ft. The company is figuring on putting in an electric light plant having about 30 arc lights, and may possibly put in a gas producer before winter.

The Meehan & Rounds Lumber Co., Siding, Miss., will erect a planing mill.

The Arcadia, La., Cotton Oil Mill & Mfg. Co. will erect a 2-press cotton-oil mill. The power plant will consist of two 16-ft. horizontal tubular boilers of 60-in. diameter and a 16x36-in. Corliss engine.

The American Fire Brick Co., Empire State Bldg., Spokane, Wash., will erect a 56x120-ft. building, partly 3 stories, for making fire brick, coke ovens, furnace block and sewer pipe. The power plant will consist of two 16-ft. high-pressure boilers of 60-in. diameter and a 100-H.-P. automatic engine.

The Modern Buggy Co., Auburn, Ind., is erecting a 4-story factory building, about 81x193 ft., and a 25x41-ft. engine and boiler room. Electricity will be used for power, and all machines will be run with motors. The capacity of the power plant will be about 65 H.-P.

The Baldwin Locomotive Works, Philadelphia, are building a 400x80-ft. addition to their boiler shop, a 4-story 180x72-ft. addition to the tank and tender shop and a 160x100-ft. power house, to have a capacity of 3,000 H.-P.

The Cleveland Cliffs Iron Co., Negaunee, Mich., is interested in the erection of a manufacturing plant in Munising, Mich.

The Hockensmith Wheel & Mine Car Co., Irwin, Pa., will erect a 225x60-ft. foundry and machine shop, 175x50 ft. blacksmith and wood shop, 2-story, 125x25 ft. pattern and storage building, 50x50-ft. power house and a 30x20-ft. office building.

The foundry and pattern-storage house of the Union Steam Specialty Co., Scranton, Pa., has been burned, and plans are being prepared for a 100x250-ft. brick building, to be equipped with an electric traveling crane. A new cupola, blower, engine, molding machine and foundry appliances will be purchased.

For ice plant at Gueydan, La., see Water.

The W. G. Browne Mfg. Co., Kingston, N. Y., makers of hardware specialties, is erecting a 2-story, 30x80-ft. brick factory with 2 story, 30x50 and 12x15 ft. additions. The company expects to use steam for power.

The Elgin, Ill., National Watch Co. will erect a 4-story and basement fireproof addition consisting of a 46x75-ft. central pavilion, with a 190x30-ft. wing on each side. The machinery to be installed will be driven by induction motors, taking current from the central power plant, which is of ample capacity.

BUSINESS NOTES.

The L. H. Prentice Co., Chicago, contractor for heating and ventilation plants, announces that it has opened a New York office at 114-118 Liberty St., which will be under the management of A. L. Canfield, who will represent the company in the territory east of and including Pittsburg.

The Boston Elevated Railway has executed a contract with the Green Fuel Economizer Co. for installing several economizers at the central power station.

Cass Harkins, Columbus, has been appointed sole agent for Central Ohio for the We-Fu-Go and Scaife water-softening and purifying systems, manufactured by Wm. B. Scaife & Sons Co., of Pittsburg, Pa.

The Ashton Valve Co., Boston, has appointed W. R. Baldwin as special sales agent, with office at the Union Trust Bldg., Baltimore.

The Garden City Fan Co. has finished erecting the buildings of its plant at Niles, Mich., and will soon have it in operation. There is a 50x100-ft. foundry, four wood-working rooms of 40x50-ft. each, a 36x40-ft. pattern vault, a cupola, two 40x140-ft. and two 40x110-ft. machine rooms, a 40x50-ft. fan room, a 26x30-ft. engine room and a 40x18-ft. boiler room. The main offices of the company will remain at 42 South Clinton St., Chicago. The company is owned by W. W. and E. D. Green.

On July 1 the Thomson Meter Co., Brooklyn, stamped its 211,218th meter; the meters are stamped only as they are sold.

The Lead Lined Iron Pipe Co., Wakefield, Mass., has been compelled to enlarge its plant to handle some large orders recently taken as well as to accommodate its increased regular business.

The electric power plant of the new United States Steel Building at Duluth, Minn., will consist of a 75 Kw Westinghouse generator direct-connected to a tandem compound engine built by the Ball Engine Co., Erie, Pa.

An electric plant will soon be installed in the Deaf and Dumb Asylum at Austin, Tex., the unit to consist of a tandem compound engine built by the Ball Engine Co., Erie, Pa., direct connected to a Westinghouse 90 Kw. alternator.

The Delaware, Lackawanna & Western Railroad Co. awarded the contract to the Pittsburgh Filter Mfg. Co. for the construction of two water softening plants of the intermittent type for the Buffalo Division. These plants will each have a daily capacity of 200,000 gals. and will be located on the ground adjacent to the pumping station. The work will be completed in about forty five days.

The Pittsburgh Gage & Supply Co., Pittsburgh, Pa., reports the following recent sales of White Star oil filters: Rockingham Co. Light & Power Co., Portsmouth, N. H.; Nashville, Tenn., Electric Light Co.; Hamburg Railway Co., Blasdell, N. Y.; P. R. Mitchell Co., Cincinnati, O.; Superior, Neb., Electric Light Co.; Kankakee, Ill., Water Supply Co.; Carnegie, Pa., Tube Co.; Silver King Mfg. Co., Park City, Utah; Army & Navy Hospital, Hot Springs, Ark.; Seattle, Wash., Electric Light Co.

THE ENGINEERING RECORD.

Volume XLVI., Number 3.

TABLE OF LEADING ARTICLES.

A Single Grade of Steel for Bridges and Other Structures 49
The Plant of the Pike's Peak Power Co. (Illustrated) 50
The Second Division of the New York Rapid Transit Railroad. (Illustrated) 52
The Hoboken Station of the United Electric Company. (Illustrated) 56
Method of Building a Long Bridge in India 57
Surveying in Central America 57
The Battery Place Building, New York. (Illustrated) 59
Ventilating and Heating the Rochester Athenaeum and Mechanics' Institute. (Illustrated). 60
The Drafting System of a British Engine Shop ... 63

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

A Single Grade of Steel for Bridges and Other Structures.

Among other subjects discussed at the fifth annual meeting of the American Section of the International Association for Testing Materials, held at Atlantic City last month, that relating to the use of a single grade of structural steel for all ordinary construction in that metal has attracted much attention. The purpose of that discussion was to discover if possible whether it is desirable or feasible to secure the adoption of a single grade of structural steel in bridges and buildings, and to extend the use of that single grade of metal possibly to at least a large portion of ships' frames and hulls. One prominent feature which characterized at first the partial use and then the exclusive use of steel in structural work was the great range in the grade of metal employed. In the early days of steel construction metal possessing as much as 90,000 to 100,000 pounds per square inch ultimate tensile resistance was at times specified. The great difficulties attending the satisfactory shop manipulation of such a metal soon excluded it from use. A high grade of steel, however, has been used, at least in some cases, for the compression members of bridges until quite recently and possibly this is true even at the present time. The erratic developments which at first followed the shop treatment of steel in bridge members in some cases, prompted the great majority of engineers to avoid those classes or grades of metal in which the amount of carbon ran comparatively high, for all those members subjected to the operation of forging. High steel under such circumstances was exclusively employed for those members subjected only to operations in which heating for forging was avoided. A lower grade of metal whose behavior under forging was more like wrought iron was reserved for eye bars or other forged members.

As experience with steel structures and the manufacture of steel structural members expanded it was found that in a great majority of cases low steel with an ultimate tensile resistance running perhaps not higher than about 65,000 pounds per square inch could be punched and riveted, under suitable conditions with nearly the same immunity from erratic results as wrought iron. It was also found that a soft or low grade of steel possessing an ultimate tensile resistance of 52,000 to 60,000 pounds per square inch made an almost ideal rivet material. Out of all those various results and others of a similar nature there have been evolved by different engineers correspondingly diversified specifications for various grades of steel supposed to be specially adapted each to its own particular class of members. The simplest resulting classification has been that in which all grades of steel are divided into "soft or low," "medium" and "high." There have not been lacking specifications in which intermediate qualities have been recognized or prescribed, but generally the three principal grades named have during the past few years covered all the steel usually employed in bridges and buildings, although a separate and higher grade of steel has been generally preferred for steel castings.

These results have naturally caused the mill managers considerable trouble and annoyance, which have indeed been shared to some extent by civil engineers. The situation has therefore led naturally, if not inevitably, to the discussion at the Atlantic City meeting of the American Section of the International Association, to which reference has already been made. The predominant tone of this discussion, as well as that of other discussions in some local organizations of civil engineers, appears to be in favor of a single grade of steel for all ordinary structural purposes as existing either in bridges or buildings, although it is not quite clear whether a considerable portion of those in favor of nominally a single grade would not except either rivet or pin steel or both from that main single grade. The tendency in these discussions has been to advocate for this standard an ultimate resistance generally varying between about 55,000 and 65,000 pounds per square inch, although there has not been unanimity in regard to these limits. It seems furthermore to be the opinion that such metal need not be drilled or reamed, and that the principal advantage to be gained from its use arises from the fact that it may be punched and riveted like wrought iron.

Undoubtedly convenience and simplicity would be enhanced both in specifications and in construction by the adoption of such a standard metal, but there are some serious considerations connected with such a step. There are many experienced engineers who probably would object most strongly to the omission of reaming of punched holes even in that mild grade of steel. Again, there are others who are by no means satisfied with simple punching and riveting to produce as high a grade of results of manufacture as is desirable. They even go so far as to believe that reaming and in many cases drilling are to be desired in the interests of improved shop results. Nor is it certain that it is yet advisable to use generally for rivets metal that may run as high in ultimate resistance as 65,000 pounds per square inch. It is also practically certain that some prominent engineers desire to secure the advantage of a high working unit stress in compression members and believe that such results can be more rationally attained with steel of ultimate resistance running from perhaps 62,000 to 70,000 pounds per square inch or, possibly higher, than from the lower grade which would constitute the single standard grade of metal. Simplicity and uniformity are certainly most desirable and valuable characteristics in either specifications, design or construction, but it may be a matter of reasonable doubt whether the effort to secure simplicity and uniformity may not be pursued too far when it excludes from use particular grades of steel that are specially adapted to certain structural conditions or to the attainment of certain necessary results. It is quite possible that the nicer and more accurate shop processes may be both judicious and economical when the design of members for long spans, for instance, is in question, and in any case the adoption of a low or soft grade of steel for rivets, and another but higher grade for the main truss members, both tension and compression, and possibly also for pins, may be too judicious to be abandoned. A steel having an ultimate tensile resistance between 58,000 and 66,000 pounds per square inch is a most admirable material for both tension and compression members in all ordinary structural work either of bridges or buildings, and it would probably give neither engineers nor manufacturers any sensible inconvenience to use it in such a field in connection with a special grade for rivets, and even another but higher grade for pins, although in all ordinary cases the higher grade would not be needed. It does not seem probable that the radical measure of resorting exclusively to a single grade of steel will find favor with a sufficient number of experienced engineers to secure uniform adoption, although it would be quite reasonable to adopt a single grade for tension and compression members in all ordinary bridge or building work.

Malaria and Mill-ponds are so closely associated, according to the Alabama Supreme Court in Richards v. Daugherty, 31 S. Rep. 934, that such a pond, although in use about ten years, has been declared a nuisance and ordered to be abated. The complainant in the case agreed to the construction of the pond originally, and advised the defendant concerning the plans, but these acts were held to be no bar to his subsequently procuring the abatement of the pond, when it was found that his family suffered severely from malaria after it was formed.

The Louisiana Purchase Exposition has such exceptional resources at its command that it will be marked by features of management that have never before been possible. The appropriation of $5,000,000 by Congress was only made after satisfactory proof had been furnished that the exposition company had raised $10,000,000, so that financially the enterprise has about double the resources at the command of the managers of the Columbian exposition at Chicago. One of the results of this condition will be the absence of all charges for floor space to machinery exhibitors, and the abolition of charges for power, light and such facilities may seem reasonably necessary for the best presentation and operation of a desirable display. With such a generous programme, however, it is necessary for the management to have full information at an early date of the extent and character of the exhibits, in order to plan the necessary facilities, and Mr. Thomas M. Moore, chief of the Department of Machinery, urges all who intend to take part or wish further information to communicate with him at once. The Manufacturing Department will be housed in three large structures. The Varied Industries Building, 1,200x525 feet in size, will contain those manufactured products in which an attempt is made to please the eye, such as silverware, furniture and pottery; the special machinery used in producing these articles will also be exhibited here. The Manufactures Building is a 1,200x525-ft. structure for displaying purely utilitarian products, such as rubber goods, plumbing materials and apparatus for heating and ventilation. The Textile Building is 758x525 feet in plan and will be devoted to materials used for clothing and allied purposes and to the special machinery for making them.

The Plant of the Pike's Peak Power Co.

By R. M. Jones, Engineer and General Superintendent.

The Pike's Peak Power Company, whose general offices are at Victor, Colo., was organized in 1899, under the laws of Colorado. The company during that year purchased ranch property, placer claims and reservoir sites on West and East Beaver Creeks, in Teller and Fremont Counties; located, developed and patented placer claims along these streams, and at this date owns by patent all of the lands on and along these streams, including reservoir sites, and all water power privileges, over a distance of 1½ miles on Beaver, 7 miles on West Beaver and 3½ miles on East Beaver. These streams are noted for excessive difference in elevation in short distances, and produce sufficient water to make of them valuable water power properties.

One of the power stations contemplated by the company, completed and in operation during the past year, is known as Station A. It is located on West Beaver, in Fremont County, 2¼ miles up the stream from the junction of East and West Beaver. The completion of this station has also accomplished much of the development and actual construction for Stations B and C, in the way of reservoir capacity and pipe line delivery of water, which is especially serviceable to the two lower stations after having been used through Station A. A description of the completed work follows:

Dam and Reservoir.—The dam and reservoir are 5½ miles east of Victor. Here is located the largest steel-faced, granite backfilled dam on record to date. The structure is 405 feet in length along the cap, 220 feet in length of base, 148 feet in cross section at base and 20 feet in cross-section at cap. The upper slope or steel face is 30 degrees from the vertical, and the lower slope 50 degrees. The height of the dam from the bed rock to the top of the sixteenth plate, at the level of the spillway, is 70 feet. The spillway is 40 feet wide, cut in granite formation and passes around the northwest end of the dam. The granite backfill against which the steel plate rests, is carefully laid as a dry wall of heavy granite boulders, usually of 20 to 80 cubic feet each, as they are broken from heavy blasting, with loose, fine granite filling the intervening spaces.

The steel face is built of sheets measuring 5x15 feet and ½ inch in thickness for the bottom, which is eight plates in height. Continuing, the plate is reduced in thickness to ⅜ inch and finally at the cap it is ¼ inch in thickness. The entire facing is riveted up with horizontal butt straps, and 4x5x½-inch angle bars placed vertically the entire length of the dam. The 5-inch leg of each pair of angle bars projects into the reservoir and constitutes a standing joint seam, with a 2x⅜-inch iron liner, riveted between the extreme outer points of these angle bars, thus making a thorough expansion joint for each section of 15 feet. The bottom and end connections of the entire sheet are concreted into a deep channel quarried out of the bed rock, and the bottom terminates in two pairs of 5x8-inch angle bars, which are riveted through the plates. The end connections are prepared in exactly the same manner, but are applied vertically. The entire facing is riveted up and calked in the same thorough manner as in boiler practice. A space of 6 inches was left between the steel plates and smooth surface of the granite backfill. This narrow space is taken up by sand, gravel and sedimentary deposit, the filling being applied with ample water and permitted to dry before water pressure was allowed to enter the reservoir.

The reservoir has a surface area of 130 acres and holds 102,000,000 cubic feet of water.

Wood and Steel Pipe Line.—Water is taken into the wood stave pipe through a "Griglay" 240 feet long, perforated, giving 30 times greater area than the pipe. The connections between the Griglay and also those between the main pipe line and the steel facing of the dam are made by steel angles.

The wood pipe is 23,200 feet long, 30 inches in inside diameter and is of 1½-inch redwood stave, banded with ½-inch steel bands and cast-iron lugs. The bands are spaced along the pipe at all distances between 2¼ and 8 inches on centers, as is necessary for resisting the internal pressure, variations being caused by various inverted syphons along the line, two of which have to withstand a head of 215 feet. This pipe line extends over fearfully rough country, about half of the grade being through original granite formation; many curves are on less than 100 feet radius, and there is one compound curve of 35 feet. The wood pipe passes through the Skaguay tunnel, which is 1,535 feet in length, located 21,000 feet from the dam.

From a point 200 feet below the Skaguay tunnel, where the static pressure reaches 220 feet, the line consists of steel pipe 29 inches in diameter in various thicknesses of plates, ranging from ¼ to ¾ inch, as required to meet the internal pressure with an ample factor of safety. The total length of steel pipe, including the receiver, is 2,900 feet, and it is on an incline averaging 38 per cent. It passes over grades constructed through a tougher granite formation in respect to roughness than ever was encountered in railroad construction in Colorado. At one point it passes through an inclined tunnel 335 feet in length, just above which is a bridge 70 feet in height, both being on 40 per cent. gradient, and at various points there are extremely deep open cuts. From the south end of the Skaguay tunnel the pipe line is entrenched in the grade on which is constructed a three-foot railway leading from the Skaguay tunnel to the power house, its grade being 1,163 feet vertical in 3,100 feet horizontal. This road is the only means of access to the power house. The cars are operated by a double-hoisting engine.

JOINT BETWEEN STEEL FACE AND CONCRETE.

VIEW OF THE DAM OF THE PIKE'S PEAK POWER COMPANY DURING CONSTRUCTION.

The upper terminus of the railroad lies under a vertical ledge 70 feet in height, and all machinery, apparatus and materials of all kinds, were lowered by boom and derrick, taking loads from the wagons at the upper landing and lowering them 70 feet over the ledge to the cars. The loaded cars were lowered by means of the friction brake on a hoist, which was equipped with a ¾-inch steel cable; 1,400 tons of building materials passed down this peculiar railroad.

Station A.—The power house is 38x98 feet in size, with two side wings of 16x48 feet each, and is located on the summit of a granite projection surfaced off true to grade. The building is constructed of brick, with a corrugated steel arch roof covered with concrete, tar and gravel; it has a concrete floor and is absolutely fireproof. It is provided with a 10-ton traveling crane..

The hydraulic apparatus was manfactured by the Pelton Water Wheel Company, of San Francisco. Each unit consists of two steel disk wheels 66 inches in diameter keyed to the same shaft and working in the same wheel house.

The base frames are built up in a box pattern of the same type and general design as the generators, to which they are connected. The frames of the water wheels and generators are faced for accurate, rigid connection to each other by bolts and dowels. The connection of the water wheel and generator shafts is effected by the hub of a 7,000-pound steel cast balance wheel banded with a rolled steel tire band 4 inches in thickness. The wheel is 7 feet in diameter.

The nozzles used to develop the required power under the 1,160 feet of effective head obtained at the station require to have a diameter of only one inch to furnish 236 horsepower, including losses. The nozzles for each unit vary in diameter, one having the capacity of the generator, and the nozzles for the other wheel in the same unit being somewhat reduced. Each wheel in each unit will furnish power for the full capacity of the generator connected to it. In operation, however, it is customary to install nozzles of such varied diameter or capacity as to enable the load requirements to be met by the use of nozzles under full pressure, and thus avoid more than a slight loss in water due to regulation for low loads. The nozzles are of the deflecting type and work under full pressure at all times, which is the cause of the variation in their diameters. The regulation is of the Armstrong type, owing to the fact that automatic regulation under the existing conditions could be only a failure. Due care has been taken to extend the apparatus for the actual control and regulation of each unit to a point directly in front of the switchboard panel belonging to that unit.

The receiver runs longitudinally through the building under the steel-concrete floor. The discharge or tail-race water returns directly under the receiver to the south or lower end of the building, at which point it will later unite with water conducted from a point 800 feet above Station A, where a catcher-dam is to be constructed, and the water diverted from the Beaver Stream channel. There is a considerable accumulation of water between the dam and Station A, and it is the purpose of the company to unite the waters through the station with the accumulation in the stream and conduct the combined waters through a pipe line to a point 200 feet above the forks of the East and West Beaver Creek, at which point there will be constructed Station B. There will be built a small pipe line up the East Beaver to the same static level as the tail-race water of Station A. The waters of both pipe lines will be united before entering the receiver. The pressure of Station B will be 1,257 feet or 544 pounds pressure per square inch. With the added accumulation of water in the West Beaver branch, 3,500 horse-power will be obtained, and from the East Beaver branch, about 2,000 horse-power, all of which may be developed at Station B.

POWER STATION A, PIKE'S PEAK POWER COMPANY.

THIRTY-INCH WOOD STAVE PIPE, 23,000 FEET LONG.

The electrical generators now in operation at Station A are four 400-kilowatt General Electric machines, three phase, thirty cycles, 600 volts, with stationary armatures and rotary fields, making 450 revolutions per minute. Two four-pole exciters have a capacity of 30 kilowatts each while running at 675 revolutions per minute, and furnish current at 70 volts, each giving sufficient exciting current for all four generators while working at full load.

With reference to the efficiency of the water wheels, it may be stated that they were guaranteed to develop 83 per cent. of power on their shafts at full load when the nozzles are in normal position. In considering the efficiency of the water wheels, the General Electric Company's generators were assumed to have a commercial efficiency of 94 per cent. at full non-conductive load, therefore with every 33,000 foot-pounds of water the water wheels will produce in current one indicated horse-power less 17 per cent. loss in the wheels and 6 per cent. loss in the generators, delivering 78/100 horse-power or 582 watts from the brush-holder terminals of the generators. These efficiencies have been fulfilled by tests. All water connections are tested to 800 pounds pressure to the square inch. In making the efficiency tests, measurements are made through the standard wier commonly used in the United States, which measurements are verified by spouting tests by working water through nozzles of known diameters.

The switchboard apparatus is especially liberal in design, and is made up of one exciting current panel, four generator panels, two distributing panels, two high tension panels and one paralleling or synchronizing panel. Each panel is made of Vermont marble, 62x36 inches in size, with a 28x36-inch sub-base, and is 2 inches in thickness; it has a complete equipment of indicating and recording instruments, switches and regulating apparatus. The main line switches from each machine are operated independently either for power or light. The circuits are arranged so that any or all of the machines may be applied on either circuit. The transformers are six 250-kilowatt air blast, of the General Electric make, having 600 volts on the primaries and 12,600 on the secondaries. The twelve complete sets of lightning arresters are of the General Electric make. The cable connections between the generators and switchboard and from the switchboard to the transformers are all highly insulated and laid in conduits in the concrete floor. Since the early operation of this station, it was found necessary to install some thorough system for combined arc and incandescent lighting, which has been fully accomplished by the introduction of two 200-kilowatt compensated three-phase generators, 60 cycles, with their full equipment. These generators have 12 poles and operate at 600 revolutions per minute. Each generator contains its own independent 12-pole exciter, built directly on the revolving field-shaft. These machines are also directly connected to impulse type water wheels.

Transmission and Distribution.—The line transmission from Station A to the center of distribution at the Gold Coin Mine at Victor includes a distance of eight miles by pole line. The circuits consist of three No. 4 B. & S. power wires, and the lighting circuits of three No. 6 B. & S. wires, which are ample to deliver 1,600 kilowatts at less than a 5 per cent. energy loss. These lines are transposed at intervals of ½ mile along the line. The poles also carry for telephone purposes two No. 10 galvanized iron weather-proof wires, transposed each 120 feet. The insulators were furnished by R. Thomas & Sons Company, of East Liverpool, Ohio. They are 5½ inches in diameter, of porcelain, and each is same up of three independent cups. In manufacture they are subjected to a 40,000 volt salt test. The line voltage is 12,600, both on 30 and 60 cycle lines.

The sub-station is a brick, steel and concrete structure, adjoining the Gold Coin ore house in Victor. All transmission circuits enter this building where the current is transformed through nine 50-kilowatt General Electric oil transformers to 115 and 460 volts secondary, for local lighting distribution connected in the Y four-wire system and also for local power work. There is also a set of three 50-kilowatt oil transformers with 350-volt secondaries, which operate a 120-kilowatt rotary converter, furnishing current for a locomotive in the United Mines transportation tunnel for ore hauling, and also for Bull Hill tunnel haulage. High-pressure distributing lines leave the sub-station in various directions after first passing through 20,000-volt oil switches, making each line independent. These branches run to Economic Mill, where about 300 horse-power is delivered, to Beacon Hill for hoists, power and lights, to the Deadwood mine where a 100 horse-power air compressor is operated and a secondary 460-volt power circuit reaches Independence, Altman and the Wild Horse districts. Another primary line reaches Cameron and Gillett, after first passing through Goldfield, all for lighting services and distributed in each of these towns through their local transformers connected in delta. Two additional primary distributing lines reach Anaconda, where independent lighting and power is distributed to the town of Anaconda and the various mines in that vicinity. These lines also reach Elkton on their way to Anaconda, where lighting is also distributed.

Extensions.—It is the purpose of the company to construct an independent transmission line from Station B to Station A and possibly an independent line to the distributing stations in Victor, including the connections through Station A, thus permitting the use of the entire energy of both stations to work in parallel over either station's lines or to work each station independently, as desired. It is also proposed that transmission lines will be extended from these stations to other localities within reach. Thus, with two complete pipe lines, pole lines and generating station systems, the most unquestioned reliability may be counted upon. It is also the intention of the company to install a third station on the combined Beaver streams at a point near the mouth of the canyon and approximately 2 miles below Station B, to be known as Station C. Here the difference in elevation is but 373 feet, but as the volume of water will probably reach 50 second feet, this could develop 2,100 horse-power less losses. The company owns also an excellent reservoir site on East Beaver at 1,700 feet elevation above Station B and but 2½ miles distant, which reservoir may be developed to excellent advantage in the near future.

The securities of the company are all owned by the Woods Investment Company, of Colorado Springs and Victor, of which Warren Woods is president, H. E. Woods vice-president and treasurer and F. M. Woods, secretary and general manager. The power company was organized and the property developed originally by the Woods Investment Company for the purpose of supplying power and light to the milling and mining interests owned and controlled by them in the Cripple Creek mining district, but the work of construction was carried out to much larger magnitude than at first intended, and therefore the company is now supplying current to other properties and doing a large proportion of the lighting in the various towns in the district.

INTERIOR VIEW OF STATION A.

The Second Division of the New York Rapid Transit Railroad.

The Second Division of the New York Rapid Transit Railroad includes sub-sections 5A, 5B, 6A, and 6B, and extends about 20,125 feet from 41st to 104th Street. It is nearly all of the standard four-track construction illustrated in The Engineering Record of January 12, 1901. The regular structure has concrete walls, roof and floor, steel columns and roof beams, and is 13 feet high from base of rail and 50 feet wide in the clear. The bents of the riveted steel framework are 5 feet apart on centers and each has a 15, 18 or 20-inch I-beam roof girder in four sections, knee-braced to the tops of five vertical columns, the two end ones being enclosed in the concrete side walls. The roof, sides and bottom of the structure are waterproofed by a continuous sheet of asphalted felt which encloses it completely and is built into the thickness of the concrete far enough from the outer surface to be protected from injury. Inside the waterproofing there is a set of sixteen four-way terra cotta electric conduits built into each side wall, and outside there are tile cross-drains under the floor which connect with longitudinal tile pipes to the sewers for the drainage of the ground-water around the structure.

There are three underground stations on this division where there are special arrangements of tracks, cross-overs and switches. At the south end of the division connection is made with the east one of the two Park Avenue tunnels by a tunnel which has a cross-section with a maximum inside width and height of about 29 feet and 18 feet respectively. This tunnel is curved in horizontal plan, is built in rock and earth, and is lined entirely with concrete without steel reinforcement. The floor is horizontal and the side walls are vertical for a height of about 7½ feet where they are tangent to the three-centered curve of the arch roof. Connection is made with the west tunnel in Park Avenue at 41st Street by the ordinary steel and concrete structure.

This division is entirely in subway and, except on 42nd Street where various tunneling methods are used, most of the excavation is done in open cuts and by drifting under the surface tracks of the electric railways. The maximum depth of excavation is about 50 feet, the minimum 20 feet, and the average about 25 feet. The total estimated quantities include about 540,000 yards of rock and 550,000 yards of earth excavation, 160,000 yards of concrete and 32,500,000 pounds of steel. The total amount of the contracts let is about $10,000,000, and the work is required to be completed by September 1, 1904. It is hardly necessary to add that Mr. William Barclay Parsons is chief engineer of the Rapid Transit Commission; Mr. G. S. Rice is deputy chief engineer; Mr. Alfred Craven division engineer, and Mr. Robert Ridgway assistant engineer.

Special pains are taken for the systematization of data and records in the division engineer's office, and no preliminary work is done in the field that can be prepared in the office. Notes, maps, profiles, tables of figures, distances and values, cross-sections and various reference data are made to uniform scale on tracing cloth and blueprinted on 5x7½-inch pages which are bound in flexible leather coyers like field books and are supplied to the assistant engineers on the different sections. These notes are very comprehensive and are carefully arranged and checked in the office so that scarcely any figuring is necessary in the field and reference marks can be found and angles and levels given without requiring more than an interpolation.

One page has a map and profile of about 800 feet of the line with survey stations, column centers, line and grade, tangent points, curb, street centers, crossings and references to the large scale drawings marked on it. The opposite page is headed "alignment and grades," dated and ruled in four vertical columns for station number, grade of base of rail, deflection and curve data, the last column giving the angular deflection for 50-foot tangents and the versed sines for 50-foot chords. Diagrams of standard and special cross-sections, plans and elevations are given and special small-scale drawings showing the essential dimensions of different portions of the work isolated from the rest, as of the foundations which show the base of rail and details of floor construction and of location and grade of side sewers and sub-drains. Standard cross-sections of steel and concrete work show the important dimensions and limiting values.

The concrete tunnel has a varying cross-section, the variable dimensions being indicated by letters on the diagram, tables are given of the successive values of the letters and of the deflections to be laid off by the instrument at successive points, so that the engineers can give any point or distance without calculation and still not be burdened with a mass of elaborate drawings or confused data. Another table is ruled in double columns, one of which, marked D, is the distance in feet from the end of the vertical curve to the point at which grade is wanted, and the other column, K is the correction to be added to or subtracted from the given tangent grade to obtain grade on vertical curve. There are many other diagrams, tables and specific data but these serve to illustrate their character and the convenience, expedition and accuracy which they secure.

The condition and progress of the work at the present and at any past time, together with the actual and comparative amounts of different classes of work done and its total cost and relation to the progress required for the timely completion of the contract are clearly shown on diagrams appended to the monthly reports of the division engineer. In one diagram the different classes of work like earth and rock excavation, concreting, waterproofing, steel delivered, steel erected, etc., are represented by their costs, which are of course proportional to their total quantities. The totals for all the items have the same ordinate but different abscissas, so that the values are rectangles of uniform height and differing widths, the latter corresponding to their varying amounts. The ordinates are divided into 100 for percentages, and every tenth point is marked by a horizontal line across the diagram. As the different classes of work are executed the percentages finished are laid off from the bottom up in successive increments, and the areas shaded for each monthly report so that the total amount of each class of work finished is evident by inspection and the amounts which have been shown on previous reports are indicated by reversed shading; as the areas are numbered it is easy to trace the progress to date. The total sums are recorded beyond the end of the diagram and, being cross added, give the total amount of work completed.

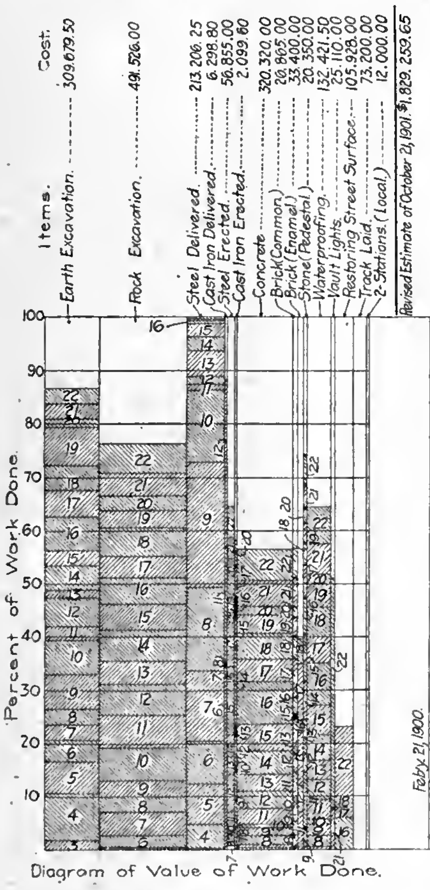

Diagram of Value of Work Done.

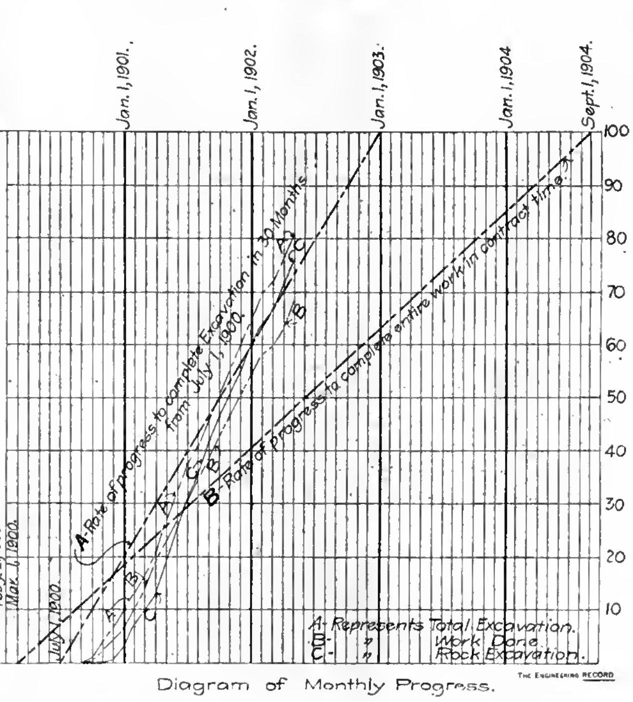

Diagram of Monthly Progress.

Diagrams Accompanying Monthly Reports of Mr. Alfred Craven, Division Engineer.

In the other progress diagram the horizontal lines are percentages of work finished and the vertical ones are the months from the beginning of the work to the required time of completion. Straight diagonal lines drawn from the origin to the 100 per cent. line indicate the regular progress which should be made to complete the contract as required. The successive percentages of work completed in different months are platted and give irregular lines which deviate from the theoretical diagonals and show at a glance whether the work is in excess or default of that required and whether the speed is being maintained, diminished or increased. This diagram shows only "total work" and "earth" and "rock excavation," the most important items which control the remainder.

In this division a large amount of preliminary work was required to move and relay gas and water mains, sewers, conduits and telephone and telegraph ducts. Such of them as cleared the finished structure were merely supported during excavation and construction and left in their original positions; others were moved enough longitudinally to clear without being disconnected; others were replaced by new lines built parallel to the old ones and connected to them to allow the original lines to be completely removed, and parts of the sewer system were remodeled.

Along the line north of 42nd Street to 73rd Street, most of the main sewers running north and south were replaced by new ones. House drains were intercepted by lines on each side of the subway which generally were run close to its outer walls and pitched both ways to outfall sewers at 45th, 65th and 72nd Streets, which had drop shafts on the east side of the subway, crossed under it in cast-iron pipes and discharged to the river through deep cuts in the cross streets. The intercepting sewers vary from 15-inch pipes at their upper ends to 32x48-inch brick sewers at their lower ends and are accessible through manholes just outside the subway walls. Generally they are carried on a rubble wall from 12 to 48 inches thick which is built from the stone excavated from the trench and serves instead of brick or concrete to protect the vertical waterproofing layer in the side walls.

Where the clearance over the subway was too small to give the proper depth for the cleaning and electric vaults for the surface car tracks and for the drains from the same, the ordinary concrete roof was replaced by horizontal 3-inch transverse I-beams 12 inches apart on centers resting on the bottom flanges of the roof beams and filled in solid with concrete between their webs to make a thin slab. By this construction, which was also used in similar places for the crossing of the gas and water mains, from 10 to 18 inches of headroom was gained. This method was used where a 30-inch water main passes over the subway at 59th Street. A few inches additional space was gained where the clearance for the vaults and their drains was very small by the use of steel plates or drip pans which rest on the lower flanges of the roof beams.

At 71st Street a 48-inch water main was branched into two 36-inch pipes to cross over the subway roof below the surface tracks, and on the other side the two pipes were again united in one 48-inch pipe. Similarly, at 66th Street, a 30-inch and a 36-inch gas main will be respectively divided into two and three 24-inch short pipes above the subway roof, and a 36-inch water main at 96th Street will be treated in the same way.

A 20-inch high pressure water main was moved about 40 feet transversely for a distance of 46 blocks. The new line was laid in sections from three to eight blocks long, temporary connections being made with the old main at the ends of a section. These connections were usually made at night to avoid the public inconvenience which would have been caused by shutting off the main in the day time. When a section was connected and put in service, the corresponding section of old pipe was removed. The sewer work was in charge of Mr. C. W. Hendrick, but the pipe and conduit work was executed by the regular staff of this division. That part of Division 2 which extends from 104th to 82nd Street is called 6 B, Mr. A. A. Sproul being the assistant engineer. From 82nd to 60th Street it is called 6 A, Mr. Bayly

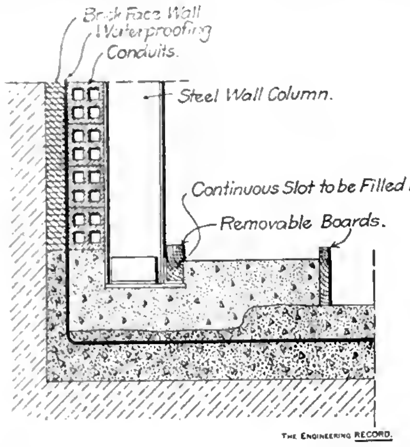
Hipkins being assistant engineer. Mr. William Bradley is the contractor for both sections and Mr. R. G. Collins is his engineer. Between 96th Street and 60th Street most of the structure is of the standard four-track subway construction.

North of 96th Street, the center tracks descend on a grade of 0.45 per cent., while the outer tracks rise on a grade of 1.40 per cent. This continues about to 100th Street, where a third track is added to each pair. The difference of levels is sufficient there to permit the upper tracks to converge, and this six-track structure continues north, with the upper three tracks immediately over the lower ones, nearly, to 103rd Street, where the lower tracks curve to the east, forming the beginning of the "East Side line" which runs under 104th Street, Central Park, Lenox Avenue and the Harlem River into the Bronx Borough. The upper tracks continue north under Broadway as the "West Side line."

Broadway north of 60th Street is much wider than most other streets in the line of the subway, and has a parkway 22 feet wide in the center over the subway, which affords space for the open ventilating wells in the subway roof. These are 7 feet wide and 14½ feet long, reaching across three panels of the steelwork and are enclosed with brick walls having pressed brick facing, granite coping and ornamental iron railings. There is one well at each end of each station and one midway between every two stations.

The excavation in these sections is made in open trench, and the two surface tracks above the subway are supported temporarily on needlebeams suspended under pairs of movable longitudinal trusses as described in The Engineering Record of March 30, 1901. Much of the excavation was through a rock fill in which it was difficult to drive the sheeting for the sides of the trench. The maximmu depth of trench was 50 feet at 103rd Street. About 50 per cent. of the excavation was in earth and fill and the remainder in hard rock. Excavation has been in progress simultaneously in twenty-six places on these two sections, and is now more than half completed and nearly one-third of the steel and concrete structure is finished. The longest completed length of steelwork is 1,130 feet between 81st and 86th Streets. The concrete for the floor is generally mixed by portable gravity concrete mixers, manufactured by the Contractors Plant Company, of Boston, which receive the aggregate at the surface of the ground and deliver the mixed concrete at the bottom of the trench. The concrete for the walls and roof is mixed partly by the same mixers and partly by hand. The principal items of the contractor's plant were enumerated in the description of the excavation already published, all the machinery below 82nd Street being operated by air pressure from the compressors installed near the foot of 76th Street. Steam plants are used north of 82nd Street.

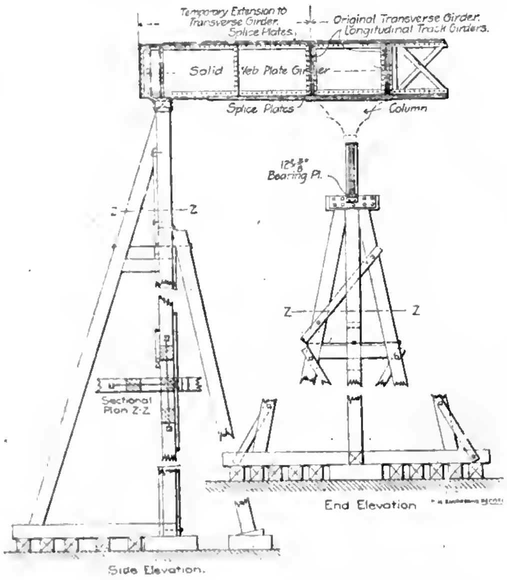
The three-track line of the Ninth Avenue elevated railroad crosses diagonally over the subway near 65th Street and four of the columns of that structure are located over the subway so that they were within the limits of the excavation and had to be relieved of their loads while the subway was constructed under them. This is being accomplished by extending the ends of the main transverse girders beyond the ends of the columns and supporting their extremities on wooden trestle bents carried down to rock in or adjacent to the excavation, as shown in the accompanying sketches. The elevated structure at this point consists of six lines of longitudinal lattice girders of spans of about 46 to 80 feet supported on transverse lattice girders of about 22 feet span and 4 feet depth. The track rails are in the planes of the longitudinal girders and the columns, about 18 feet high, are in the center lines of the outside tracks. The end panels of the transverse girders have solid plate webs and terminate at the connections with the outside longitudinal girders, where the temporary solid-web extension about 13 feet long was spliced with double web cover-plates like fillers under the web connection angles to the longitudinal girder and



Detail at Lower Corners, Standard Section.

with three thicknesses of flange cover plates of different lengths on the top and bottom chords, all thoroughly field-riveted and painted. About 18 inches from the end the girder extension was seated on a 12-inch bearing plate on the longitudinal cap of a wooden tower or trestle bent which had one vertical post and three batter posts converging to a solid cross-section at the top and extending to a triangular base about 16 feet long and 12 feet wide with sills supported on short transverse grillage beams. A fourth batter post was set at the bottom of the bent making it a rectangular pyramid there, with 12x12-inch main timbers braced with diagonal planks, horizontal struts and tie bolts.

As the side walls of the subway also act as retaining walls special care was taken to provide for resisting the lateral thrust at the bottom, and provision was made for it in laying the concrete floor. The first layer, about 7 inches thick, was laid over the full width of the excavation. The 4-inch outside protection wall was commenced on the edge of the footing and a fillet turned in the angle to provide a rounded seat for the waterproofing. The waterproofing was placed on the bottom and flashed up on the side of the wall. A second layer of concrete, about 7 inches thick, was laid on top of the waterproofing, finishing the floor to about 4 feet from the outside of the wall where a vertical shoulder was left and the waterproofing was covered only about 4 inches deep, as shown in the diagram. After this concrete was well set a concrete bench 12 inches deep was laid with a continuous trench in its surface to receive the column bases. Then the 12-inch I-beam vertical wall columns were erected and bolted down, and finally the spaces on both sides of them were filled with concrete above their base plates, enclosing the feet of the columns up to the level of the top of the bench.



Support for Ninth Ave. Elevated Ry.

After the erection of the steelwork the panels between the wall columns were filled with vertical arches made of concrete rammed in between the electric conduits and short vertical sections of wooden centers hook-bolted to the inner flanges of the column I-beams. Each centering section was made of vertical lagging strips 3 feet long nailed across three horizontal scarf pieces 1½ inches thick. The sections were successively set from the bottom up and were so smoothly made and fitted that they left a neat and satisfactory finish on the surface of the concrete. The roof arches were laid on similar centers suspended from the roof beams. Wherever a horizontal point in the concrete was formed by the meeting of different days' concreting a 2x4-inch horizontal strip of wood was bedded in the edge of the part finished first and after it had set was removed, leaving a groove into which a tongue of the concrete of the next part bonded itself and made a strong connection between the two parts.

That part of Division 2 which extends from 60th Street to 47th Street is called 5 B; Mr. John H. Myers is assistant engineer; Naughton & Company the contractors, and Mr. C. W. S. Wilson is the contractors' engineer.

Here there are two surface tracks close together, symmetrical with the center line of the subway on tangents. During construction they were supported on needlebeams shored up by vertical timbers from the bottom of the excavation, which was made in open trenches generally on one side of the surface tracks. As a rule one-half of the structure was completed and the backfilling done before the opposite side of the street was opened, this method being followed to avoid interference with public traffic any more than was absolutely necessary. The first operation was to excavate to rock between the surface tracks and the east or west curb as shown at the north end of the plan. The water mains, gas pipes, electric conduits, etc., were carried on horizontal timbers having their outer ends let in flush with the top of the asphalt paving, the inner ends resting on the concrete covering of the ducts for the surface tracks. Drifts were run under both tracks about 10 feet apart, and 12x12-inch needlebeams about 25 feet long were laid in them ready to support the tracks when the earth was excavated underneath; their outer ends were supported on vertical shores set at first, on the surface of the rock as shown in section Y Y. The excavation was then continued through the rock to the sub-grade with a face diagonal to the axis of the subway. After reaching rock in the side trench the excavation was continued under both tracks by lateral extensions and when a sufficient width and length was completed the concrete floor was laid and the steelwork was erected for one-half of the subway. The masonry piers were built on the finished roof of the subway, one surface track was supported on them and the street surface restored to the curb. Then a trench was excavated to rock on the opposite side of the surface tracks and vertical shores set in it to support the ends of the needlebeams. Finally the rock was excavated in the bottom of this trench and the subway structure completed and the second surface track supported on it. The rock and earth excavation was made with oblique faces in the side trenches and with longitudinal faces under the tracks, and all shores were successively replaced by longer ones as the excavation was deepened around them.

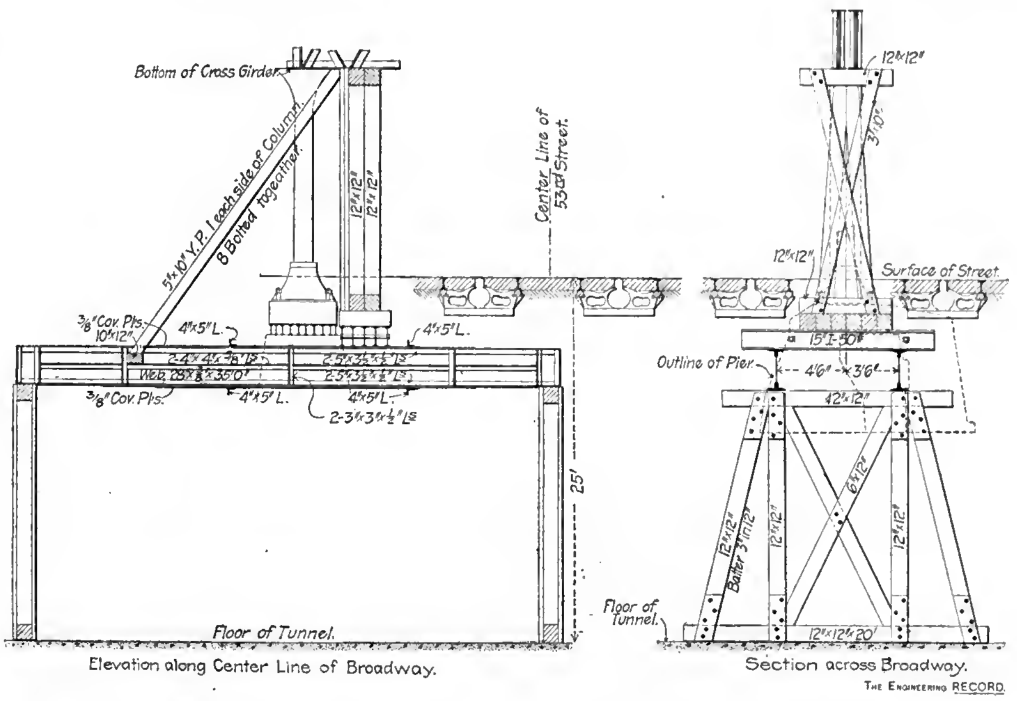
The elevated railroad crosses the subway at 53rd Street and two of its columns are located between the surface tracks of the Broadway lines above the subway roof. To support this part of the structure temporarily while the subway was being constructed and piers built on its roof for the columns bases, the main elevated girders were carried on wooden columns or towers and the foundations of the columns removed preparatory to replacing them on the new piers. The temporary columns were meanwhile carried on pairs of girders just below the street level which were set each side of the old column and pier, and were supported on trestle bents seated on the subway floor, as shown in the sketches. Open trenches about 6 feet wide, were excavated across the line of the subway about 17 feet each side of the column which was to be removed, the finished subway concrete floor was built in the bottoms of them and on it were set the trestle bents each composed of two vertical and two batter posts with caps and sills, all of 12x12-inch timber bolted together with scabs and braced by 6x12-inch diagonals. Two 28-inch steel plate girders, 35 feet long, which had previously been used by the same contractor for the underpinning of the Columbus Monument, as described in The Engineering Record of July 27, 1901, were set across their caps, 8 feet apart. One side of the column pier had to be cut a little to clear one of the girders and the other girder was put through a hole in the pier which had originally been made to receive 12 and 20-inch water pipes recently removed. Each side of the pier the girders were connected transversely by sway brace frames made of horizontal angles riveted across their flanges and X-brace angles riveted to the horizontal angles. A grillage of five 15-inch I-beams, bolted together with separators, was set across the top flanges of the girders close to the old column pier and on it was placed the temporary column consisting of two vertical and two inclined 12x12-inch timbers with horizontal caps, sills and footing timbers and diagonal braces securely bolted together. The top of the column was braced by an inclined post to the plate girders and the transverse girder of the elevated railroad structure was jacked up 1 inch. Wedges were driven between it and the cap of the new column, the jacks were removed, and the pier of the old iron column taken out.

The excavation was then completed between the two trestle bents, the subway structure built there and on its roof a new concrete masonry pier built to carry the old iron column and its estimated loads of 40,000 pounds dead and 100,000 pounds live weights.

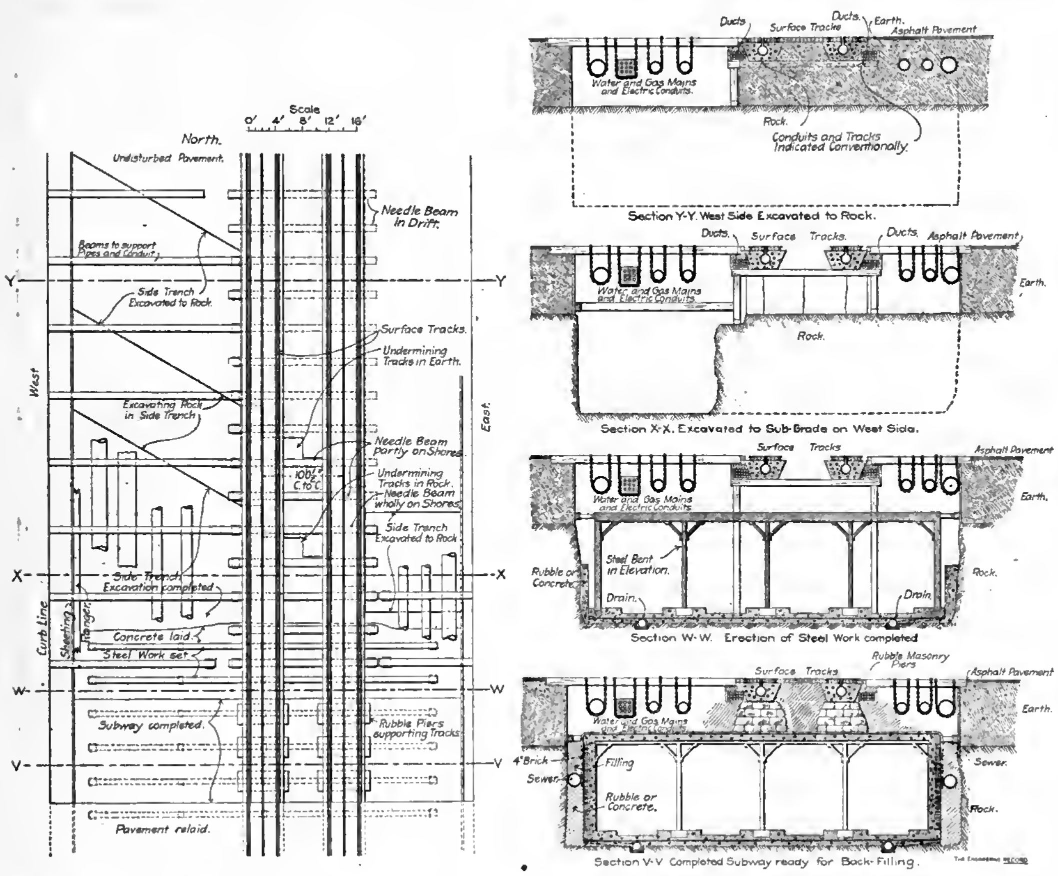
After the south column had been thus underpinned a transverse trench was dug 17 feet north of the north column, the south trestle placed in it, the girders moved north across the other trestle to rest on it, and the north column was underpinned as has been described for the south one. The temporary columns were braced transversely as the excavation was extended below them, and they showed a settlement of only 1/8 inch and no serious vibrations under the constant train service which was maintained above them with little reduction of ordinary speed.

On this section of the subway the excavation is now 90 per cent. completed and about three-fourths of the steel work is set and concrete walls and roof finished to correspond. The 50th Street station is half finished and the 60th Street station is nearly completed. The passenger platforms where under the sidewalks are roofed with the Tucker & Vinton patent vault lights set in concrete reinforced with Ransome twisted steel.

(To be continued.)



METHOD OF SUPPORTING ELEVATED RAILWAY AT FIFTY-THIRD STREET.



SEQUENCE OF OPERATIONS ON DIVISION 2, NORTH OF FORTY-SEVENTH STREET.

The Partial Failure of some concrete piers of a bridge crossing the Sanitary District Canal at Joliet on the line of the Chicago, Rock Island & Pacific Railway occurred during a severe flood on June 2 and 3. The bridge is about 600 feet long and crosses the canal on a 30-degree skew. In 1899 the Sanitary District Trustees built a pier and an abutment for the bridge, and these were not injured. Last year the railway company replaced the superstructure with plate girder spans and rebuilt the old cylinder piers. Cofferdams were constructed about these cylinders, which rested on rock bottom, and after placing forms about the old piers concrete was rammed around them so as to make much larger piers oblong in plan and without any cutwater. When the forms were taken off it was found that the concrete at the base was partly gone and the defect was repaired by replacing the forms and slushing concrete into the voids. During the storm one of these piers was pushed downstream 18 inches and tipped so that the lower edge was 12 inches below that on the upstream face. This tipping continued steadily until it amounted to about 5 feet in the course of a week. The other reconstructed piers suffered in a similar but less pronounced manner. The failure was evidently due to the defective bond of the old and new concrete.

The Hoboken Station of the United Electric Company.

The Hoboken station of the United Electric Company of New Jersey is of interest chiefly because of its being a remodeled plant, the changes in equipment having been made while the usual service was continued without interruption.

The old plant embraced two vertical Corliss engines, one horizontal Corliss and two small McIntosh & Seymour high speed cross-compounds. The high-speed engines were direct-connected to generators, but the greater part of the power was transmitted by belts from the large engines to dynamos of various kinds, in many cases passing via countershafts. None of the generators was very large, and the amount of leather belting used was enormous. The present service comprises 550-volt railway circuits, 2,200-volt two-phase alternating power and lighting circuits, and constant-current arc lighting. The power losses were so great with the old equipment that it was found necessary to change over the entire plant.

The building was extended, the part marked A B C D on the plan being the new portion, and additions to the plant were made in this extension.

There are five Babcock & Wilcox water-tube boilers of 520 horse-power each, normal rating, set in a continuous battery. They are all equipped with Roney mechanical stokers. Three sets of stokers are operated by an 8-horse-power Westinghouse engine, and the remaining two sets by another.

The feed-water heating arrangements consist of a primary heater made by the American Pipe Bending Company, of 1,000 horse-power rated capacity, and a 2,200-tube Green economizer. The feed water is taken from the city mains and passed through the Crown meters. From these it goes into the boiler feed pumps, of which there are two. One only is needed to supply the boilers, the other being a reserve. They are Worthington duplex compounds, 8, 10 and 7x12-inch, with a 4-inch discharge to the heater.

The exhaust from the condenser and feed pumps is carried to the heater and there used to raise the temperature of the feed water to about 175 degrees Fahrenheit. The water then passes to the economizer, which is built up above the top of the boiler settings and through which the hot gases of combustion pass, heating the water up to about 250 degrees.

A main distributing feed pipe runs along above the front of the boilers from which 2½-inch pipes are tapped and pass into the front ends of the boilers.

Two Buffalo Forge Company fans for draft are set above the boilers on a level with the economizer. The impeller wheels are 14 feet in diameter by 6 feet wide. Each is driven by a 12x16-inch horizontal engine, the speed varying from 30 to 110 revolutions per minute, according to the demand on the boilers. Their speed is hand controlled from the boiler-room floor. One fan only is required to produce the necessary draft, the other being a spare.

The smoke breeching is provided with a sliding door by means of which the gases may be passed through either fan. From the fan the smoke and gases go into the stack, which extends only 30 feet above the boiler room roof. Its diameter is 18 feet.

Of the old engine equipment only one unit has been retained. The 26 and 48x54-inch horizontal cross-compound Corliss engine is still kept belted to two General Electric railway generators of 500 kilowatts capacity each, which are held in reserve for emergencies.

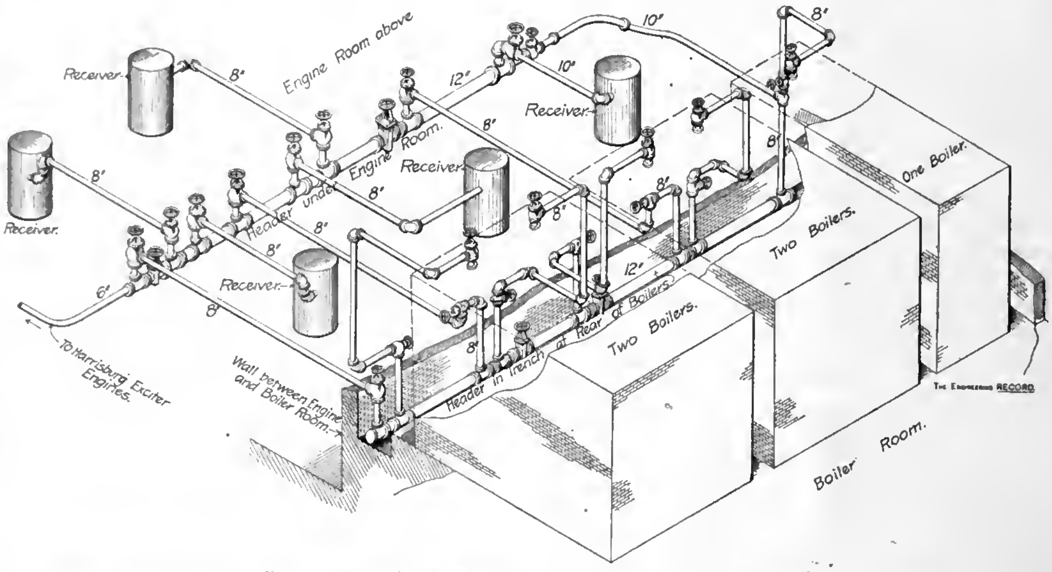


DIAGRAM OF STEAM PIPING IN THE HOBOKEN STATION.

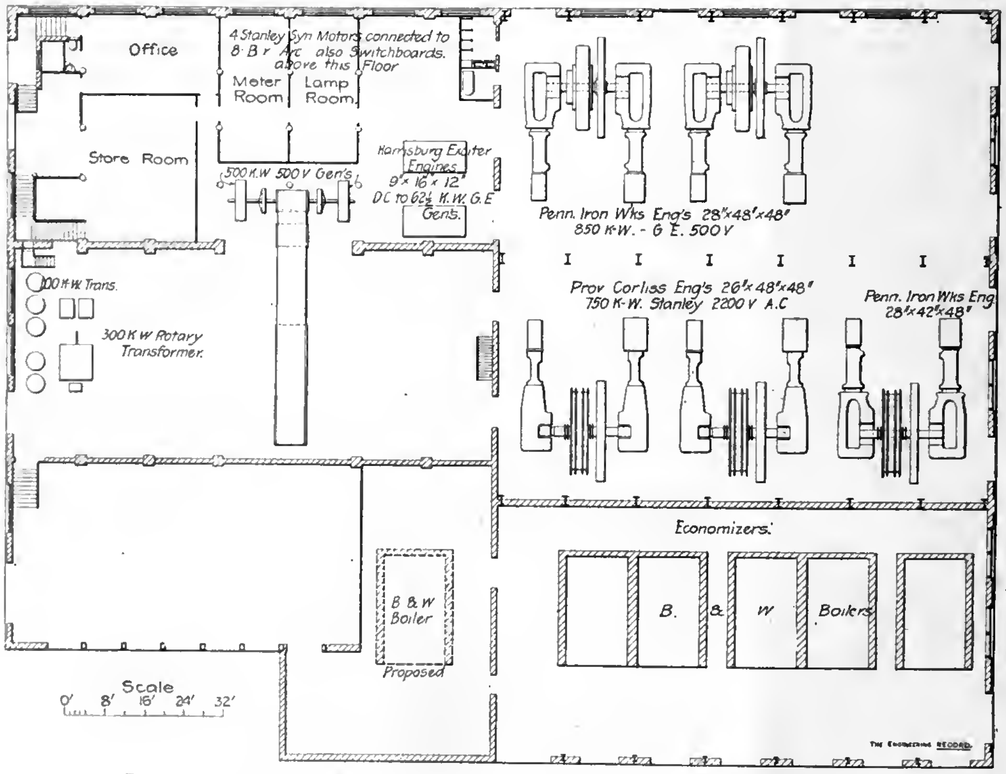


PLAN OF THE RECONSTRUCTED HOBOKEN STATION, UNITED ELECTRIC CO.

The engines in the new plant are all of the horizontal cross-compound Corliss type. There are two 26 and 48x48-inch Providence engines direct-connected to 750-kilowatt two-phase Stanley alternators, and three 28 and 48x48-inch engines built by the Pennsylvania Iron Works Company; of these last, two drive General Electric 850-kilowatt railway generators and one drives a 750-kilowatt two-phase Stanley alternator. These last machines are excited by two General Electric 60-kilowatt 6-pole engine-type generators, each driven by a Harrisburg 10 and 18x12-inch tandem compound rocking-valve engine running at 280 revolutions per minute. The large engines all have a speed of 90 revolutions.

There are five independent jet condensers located beneath the engine room floor, which is 10 feet above the condenser pit floor. Four of these are 8, 16 and 24x24-inch Deane tandem compounds and one a Worthington 9, 14 and 19x15-inch duplex tandem compound. Condensing water is brought from the river in a 20-inch cast iron main, and the 10-inch condenser injection pipes are tapped into it at proper intervals. The discharge from the condensers is carried by means of individual 12-inch discharge pipes to a common discharge main, 20 inches in diameter, which empties into the river. The exhaust steam from the engine ends of the condenser pumps goes to the heater, as before mentioned.

The steam-piping layout is somewhat unusual, as may be seen by referring to the diagram of the layout of the system. From the steam drum of each boiler an 8-inch pipe starting from the nozzle—which is connected to a dry pipe inside the boiler—passes through an angle valve to the side of the boiler wall and then downwards, tapping into a 12-inch main header which lies in a trench below the level of the boiler room floor. These supply pipes pass through angle valves near the header, so that both ends of these pipes may be closed. The header is divided into three sections by two gate valves as shown. Two boilers deliver steam to each of the end sections and one to the middle section. A second steam header runs underneath the boiler room floor parallel to the first header. It is a 12-inch pipe, divided into two sections by a gate valve. It is connected to the first header by four pipes, of which three are 8 inches in diameter and one 10 inches. These lateral connecting pipes are provided with angle valves at both ends, and consequently may be shut off from either header or from both. From the second header branch pipes are carried to each engine receiver. These receivers are merely large shells with baffle plates inside and act both as separators and storage reservoirs. Each is placed directly beneath its engine, and consequently there is always a supply of dry steam available for sudden overloads.

The two Harrisburg exciter engines are also connected to the second header, the pipes to these engines being 4 inches in diameter. Owing to their location the connection is not shown in the drawing.

All the piping and fittings are extra heavy and all joints and connections flanged. The valves are of various makes, Chapman predominating. They are all controlled from the engine room floor above by means of hand wheels and rods supported by handsome floor stands.

The system was installed in part by Westinghouse, Church, Keer & Company and partly by W. K. Mitchell & Company of Philadelphia, and the covering was furnished by the W. H. Johns-Manville Company. In addition to the steam and condenser piping mentioned there is a main free exhaust pipe leading out into the air, into which the exhaust from any engine may be turned at will. The valves making this connection are also controlled from the engine room floor.

Of the five large separators four are 4 feet in diameter and 6 feet in length and one is 3½ feet in diameter and 6 feet long. All drips from the steam pipes and separators are trapped and returned to the boiler by the Holly system.

There is no provision for coal storage at present, but bins and a system of coal handling machinery are to be shortly installed. This will include a trestle and conveyor from the river, so that coal may be unloaded direct from boats. Conveyors will also elevate the coal to the bins, whence it will be fed directly to the automatic stokers, passing through automatic registering scales.

The engine room is traversed by two 25-ton hand-operated overhead traveling cranes, each being one-half the span of the room. These were made by Alfred Box & Company of Philadelphia.

The station switchboard is so located that the engine driver cannot see or communicate with the switchboard attendant, and in order to properly control the plant a system of signalling has been devised by Mr. H. D. King, the superintendent. High up at one end of the engine room, and plainly visible from any point, is a large glass sign with illuminating lamps behind it. On this sign are engraved the directions, such as "stand by," "slow down," "stop," "start," and in the lower right hand corner are the numbers 1, 2, 3, 4 and 5, referring to the correspondingly numbered units. At the switchboard is a small box with levers projecting through the top which are properly labelled. The switchboard attendant throws the small lever corresponding to the number of the unit he wishes controlled, and that number is illuminated on the sign in the engine room. Levers also light up such directions on the sign as he may wish to give, all directions referring to the unit of the same number as that illuminated on the sign. This system is rapid, effective and seems to be in many respects better than the usual method of motioning to the engineer from a visible switchboard gallery.

The Coating of a Riveted Steel Main 48 inches in diameter, laid in New Bedford in 1896, was found to be almost as good in 1901 as when new, only an occasional blister in the asphalt in the bottom being detected.

Method of Building a Long Bridge in India.

The East Coast Railway from Madras to Calcutta crosses the Godavari River at Rajahmundry, 40 miles from the sea, on a single-track steel bridge 9,000 feet long between abutments. There are fifty-six 150-foot deck lattice-girder spans and one 40-foot span supported on six caisson piers and 50 brick well piers. Two of the caisson piers were sunk 28 feet into the sandstone by the pneumatic process. These caissons were built on shore, launched from ways supported at the river end on sand bags built up several feet to just below water level. They were lowered between pontoons from transverse beams across the tops of towers built on their decks. The other caissons were sunk by dredging through pairs of 10-foot circular openings. The brick well piers were all sunk by steam dredges suspended from gallows frames on top. The dredge buckets were toothed and the clay was broken up in advance by heavy rail-chisels. Most of the wells were sunk 20 feet into stiff black clay which was generally so impervious that the water could be bailed out and the work executed dry. When the excavation had been carried 20 feet below the cutting edge dynamite was used to loosen the clay and bring the brick shell down. The piers were filled with concrete lowered in automatic buckets with bottom flap doors.

Each span has two riveted girders 14¼ feet deep and 8 feet apart on centers which weigh 46 tons each. The top chords have semi-cylindrical bearings on fixed and roller shoes on top of the masonry, and the solid floor consists of heavy corrugated decking 14½ feet wide.

The girders for the water span were assembled on shore and moved along falsework ways to pontoons by which they were floated to the piers. There they were lifted about 30 feet vertically, moved about 11 feet transversely and lowered to bearing on the pier tops. Temporary horizontal brick platforms were built on the offset courses just above water level at the ends of the oval piers, and cantilever rails, built into the sides of the permanent upper part of the brick pier for anchorage, were supported on them and projected beyond their outer edges to support the vertical posts of a transverse gallows frame for the hoisting apparatus.

The posts of this frame were 45 feet long and 36½ feet apart, and were connected by a pair of 16-inch I-beams seated across their tops 7 feet clear of the pier coping. Each post was built of two 12x12-inch timbers clamped together and was trussed on the wide sides with 1½-inch rods in vertical planes parallel to the bridge axis and guyed on the other side by wire ropes from the tops to anchorages in the vertical plane of the longitudinal axis of the pier. The I-beam caps were 16 inches apart on centers and had clearance between their flanges for the vertical suspenders for the ends of the girders. The upper ends of these were supported on a horizontal yoke-beam 3½ feet long, in the plane of the gallows frame, and about 2½ feet above it in the clear. This yoke-beam was seated in the middle on top of a hydraulic jack which had a special base with bearings for four transverse rollers traveling on the top flanges of the I-beams. There was one suspender 16½ inches each side of the center line of each jack. The two 6x½-inch bars forming each suspender were riveted together flatways, with spacers 11½ inches apart and were made in 5¼-foot pin-connected lengths. They passed between the ends of two 12-inch channels 6 inches apart in the clear, which formed the yoke-beam on top of the jack, and were supported by flat steel keys which were slipped through them edgeways between the spacers and rested across the top flanges of the yoke. The lower ends of the suspenders had nuts bearing on lugs bolted to the lower flanges and webs of the top chords at the ends of the girders.

There was about 5 feet clearance between the posts of the gallows frame and the ends of the pier masonry, and in these spaces the end girders were raised to the tops of the piers, close up to the I-beams, by successively pumping up the jacks, inserting keys in the chains above the beams to support the girder while the jacks were released, and then lowering the plunger and yoke for another stroke, and so on. The suspenders were thus successively supported from the yoke while the girders were lifted and from the cap-beams between lifts. As the girders were raised the upper sections of the suspenders were removed. About 21 hours were required to raise the girders to the tops of the gallows frames. Then their jacks were rolled towards the center of the pier where the I-beam caps were spliced and supported from the masonry on a pony trestle bent, and the girders were lowered to the required position on their permanent seats.

The land span girders were assembled in a vertical plane on the ground between the piers and were hoisted into position in about 1 hour each, with wire rope tackles suspended from gallows frames seated on top of the piers. The gallows frames were 20 feet high with double posts and caps, the latter 33 feet long. The caps were 5 feet apart, supported on top of posts 13 feet apart in vertical planes parallel to the longitudinal axis of the pier. The posts had transverse sills 14 feet long with diagonal braces from their ends to the cap-beams. The cap-beams overhung the post centers 10 feet at each end and were braced by diagonal struts from their extremities to the feet of the posts. The ends of the cap-beams were anchored to the ground by ¾-inch adjustable guy chains. The hoisting tackles were operated by sweeps set on the ground near the piers. Each end of each truss was hoisted by two tackles suspended between the ends of the cap beams from rollers which rolled back on short lengths of track rails to traverse the girder to its seats after it was raised above the pier-top. Fifty-four spans, weighing 7,668 tons, were erected and completed in 8½ months. The bridge was designed and constructed by Mr. E. T. G. Walton, engineer-in-chief under the Government of India, and was illustrated in recent issues of London "Engineering."

Surveying in Central America.

There has always been a sort of fascination about surveying operations in the tropics which lends interest to even the dry official reports on such work. This is particularly true of the surveys in Central America to furnish information concerning the practicability of various ship-canal routes, articles concerning which have appeared in this journal on November 19, 1898, and September 29, 1900. One of the engineers most actively engaged on this work since 1888 is Mr. Boyd Ehle, who has a paper on the problems and methods of the Isthmian canal surveys in the "Transactions" of the Association of Civil Engineers of Cornell University for 1901-02. In a general way the operations were similar to those preparatory to railway location in the United States, but various modifications were necessary owing to the special local conditions. The organization of the engineering department had a chief engineer at the head, under whom were division and assistant engineers. The latter were in charge of a party in field work, or a section of construction. A survey party had two instrument men, a level rodman, two chainmen, a cook, helper, and about eight machetemen, as a minimum. In new country the assistant engineer was supposed to scout the work ahead of the instrumental survey, using hand instruments and perhaps pacing distances. To get the best results a clinometer was used and a chart giving the pacing reduction for various slopes. With a small protractor it was possible to make a map and sketch on the topography. A machete was, of course, the most essential part of the outfit, without which progress was well nigh impossible.

Much valuable information could be easily and quickly secured by these preliminary examinations, and if results justified a detail survey, a compass or transit lines with levels would be run through paths cut by the machetemen and the line cross-sectioned for a considerable distance on each side, so that in case of a probable canal location, this could be projected on the map. Usually the field work was mapped out on a scale 400 feet to an inch and 10 feet contours, but in the more important work at the lock and dam sites, 100 feet or 50 feet to an inch was used. The topography of large tracts was thus developed in order to cover thoroughly the area of comparative feasibility. No comprehensive idea of the whole problem could be secured except from maps, for the field work was somewhat like surveying in the dark, as far as the physical characteristics adjacent to the line were concerned.

There was, however, a great difference in the amount and character of the work of the various assistant engineers, due, Mr. Ehle says, both to method and energy displayed. A certain man seeking out a ridge or canal location would try to make a checker-board survey of the whole country in question and pick out his results on a map, while another would carefully scout out the work on the ground and direct the survey at once to the desired results. The latter was the more valuable man, but it required greater physical energy on his part. Often an assistant engineer simply kept his men at work while he remained in camp, ran the party and submitted results.

In the surveys of the impounding ridges for the basins it was considered best to determine the general direction and follow that compass course until it ran off the heights into a water course, and then offset back up a branch to the divide again and start over.

In a canal survey it is important to get the shortest distance with the least elevations, and this usually led into valleys and swamps where the work was disagreeable, difficult and unhealthy, not to mention the attention of the myriads of mosquitoes and other insect pests. Transit location surveys never averaged one-half mile a day, while compass and cross-section work usually averaged less than 5,000 feet per day, with a maximum of about 8,000 feet per day.

In a river survey, stadia methods were used for fixing the points along the bank, and the soundings located from these by the stadia or sextant. With the sextant the boat was usually run on a range and the soundings taken at time intervals. The line was assumed straight between the sextant observations, which is only possible in still water. With the stadia it is possible to locate each point more quickly and accurately. Stadia or gradient methods were of little use in the forests, and the chain was usually depended on for distances. Triangulation surveys were used on Lake Nicaragua, but were not effective on the San Juan or other rivers on account of the great difficulty of clearing out the overhanging trees along the banks.

In a reconnaissance along the coast of Darien, two sextants were used to establish the position and elevation of points on the distant mountain range and the contour sketched. The distance between the observers was determined by observation on the mast of a ship. The results, although somewhat crude, answered the purpose, and were secured very quickly and cheaply.

In the investigation for foundations and classification of material various methods were used. The earth auger was the most simple and least satisfactory, as it was difficult to manage at any great depths, and when stone was reached it was the limit of the boring and in no wise conclusive that this indicated rock in place.

The Pierce machine, with its facilities for driving, casing and washing up light material, succeeded the common earth auger. With this when stone was reached it was customary to lower sticks of dynamite and explode them by an electric battery, which usually was sufficient to displace ordinary boulders. If this was not effective the diamond drill was used to get deeper and obtain a core of the material. On the Panama canal deep test pits were used, and even a tunnel to determine the substrata.

The various classifications of material were obtained from samples preserved by the boring foreman in small bottles, if earth or of rock by taking a section of the core. These were labeled with the location of the hole and depth in feet at which they were taken, and shipped to headquarters for use in classifying the material on the cross-sections for estimates or determining questions of foundations.

Gauging stations were established at important points on the various canal routes and around the watershed of the water supply for the summit level. The observers were required to keep a careful record of the rain gauge, river gauge, and thermometer, also to make gaugings of streams with the current meters. Sediment observations were also conducted on the more important streams by lowering a sediment box and ascertaining the quantity of material moved in a certain period. Current meters were rated by moving them at uniform velocity in still water and plotting the results as a curve. The meter was then used with a boat that was anchored at points along the cross-section of a stream, if this was possible. It was sometimes necessary in large rivers in flood, to rig a cable over the stream. On this was hung a car from which the observer used his meter. The results of the rain gauge observations were plotted to give zones of rainfall, which were variously colored. These data and the river gauging observations were necessary in the very extended computations to ascertain the sufficiency of water for the lockage, and also the proper measures to be taken to regulate the floods.

The camps were usually sheds with a roof of palm leaves which were lapped similar to shingling; side walls were not necessary. Canvas tents were not a success, as they were soon ruined by the mildew of the damp climate of the rainy season. The beds were of a piece of canvas with poles through the side loops, and raised on crotched sticks. The kitchen arrangements were very simple: crotched sticks with a cross-bar were used to hang the kettle over the fire, or sometimes a rough fire place of large stones took the place of this.

In the rainy season it was first the custom to attempt to dry wet clothes with Sibley stoves, but after several dry houses were burnt with their contents, this was not in favor; it was found that no ill effects were experienced from wet clothes, although it was not unalloyed pleasure to get out of warm blankets into cold wet clothes. In the evening, on returning from work, it was customary to take off wet clothes, have a bath and get into pajamas. In mosquito infested camps, this was followed by getting under the mosquito bars as soon as possible after supper. It was sometimes necessary to do office work under mosquito bars.

The office work in the field was usually somewhat crudely done, merely to verify the accuracy of the work and its completeness. Duplicate copies of notes were made and sent to the division or chief engineer's office. At headquarters the field work of the various parties were combined into large contour maps somewhat elaborately drawn. On these large contour maps the various projects were laid out and studied. A paper location would often be sent to an assistant engineer to be run out and verified. When all the data were in, estimates were made by taking cross-section notes from the map, plotting these with the classification of material obtained from the boring notes, and obtaining the yardage by the planimeter measurement. Maps were plotted and surveys adjusted by the method of latitudes and departures. Courses were generally referred to the true meridian in transit work, checking this by the needle course. From star observations it was possible to get latitude co-ordinates for the maps. Longitude was obtained by carrying chronometers from Panama, which had been very accurately located by direct observation as a primary point by a French astronomical expedition.

By means of these map co-ordinates it was possible to combine the new work on small scale maps with those of the coast survey and other expeditions. For this work the large maps were pantographed down; usually each set of maps was reduced one-fourth, although this was not strictly adhered to. In the Darien survey the field maps were 1/12000, the general map of a route 1/60000, and the general map of all the routes 1/300000. The general map of the Panama route was made 1/100000, the profile had a similar horizontal scale with a vertical scale 1/1000. The general map of the Nicaragua route had a scale of 1/506880, the sheets of general topography 1/57600, and the detail topography 1/19200; on these latter sheets were placed the boring records. Plans of structures were made 1/480, 1/960 or 1/100 as was necessary to show details.

The Macadam Pavements of Winnipeg, Man., were repaired during 1901 at an average cost of 4.18 cents per square yard, as stated in the report for that year of City Engineer H. N. Ruttan. Formerly the macadam consisted of broken stone 10 inches thick at center and 8 inches at the sides, the first course being limestone and the top 3 inches of trap. Now, however, limestone only is being used. During the year nearly 33,000 square yards were laid at a cost of about 74 cents per yard.

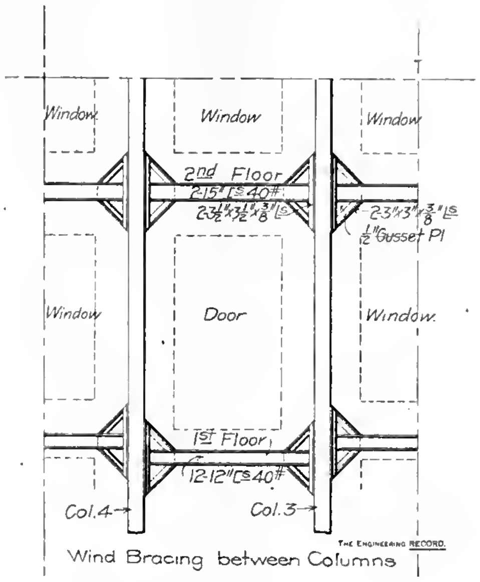
The Description of the North German Lloyd Piersheds recently printed in this journal contained a few errors. The weight of the roof in the cut on page 579 is stated per square yard but should be per square foot. The theoretical range of expansion of the sliding joints mentioned on the same page is 1½, not 1¼, inches. The flooring of the second-story is a 3-inch first layer and a 1¼-inch second layer of pine, instead of 2 inches all told, as stated on page 579. On the next page the height of the upper section of the doors should be 10 feet instead of 12 feet for piers 1 and 2 and 11 feet for pier 3. The leader mentioned on page 611 is 4 inches, not 4½ inches.

The Battery Place Building, New York.

The Battery Place Building is a twenty-story steel-cage office building, 255 feet high from basement floor to roof, which has a frontage of 181 feet on Battery Park and 63 feet on West Street. The principal contracts have been let, the work on the caissons and substructure is well advanced and it is expected that the building will be ready for occupancy next May. There are in the framework 53 riveted steel columns with rectangular closed cross-sections built of two channels and two or more cover plates. They are seated on 48 concrete piers carried to bed rock in steel pneumatic caissons, as described in The Engineering Record on June 21. Most of the piers are cylindrical with steel shells or cofferdams extending to about 2 feet below the basement floor and having circular granite cap-stones 20 inches thick and 6 inches less in diameter than the pier, bedded in the concrete and projecting 2 inches above the top of the shell. A second granite cap-stone 2 feet narrower than the first, is bedded on it and receives the cast-iron column base which nearly covers its surface and has its lower flange bedded in the concrete of the basement floor.

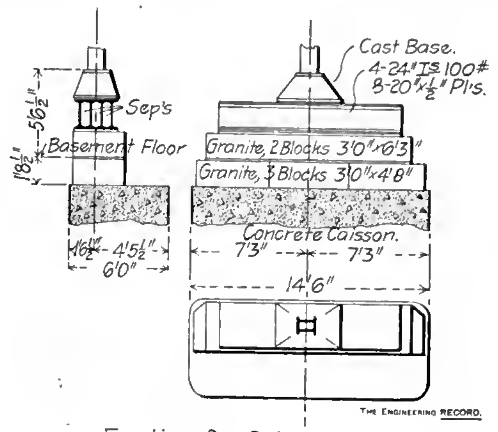
There are sixteen rectangular piers with rounded corners, four in the center of the building and two in the front wall-column line which are symmetrically loaded with two columns each; two more in the front wall-column line which have a single center column each, and eight in the rear wall-column line which are eccentrically loaded with one column each. The twin columns on the front wall piers are 31 inches apart on centers and are seated on the upper course of granite cap-stones. The rear wall-column piers are filled with concrete to the tops of the steel shells and have two courses of thick, large, rectangular granite capstones close to the outer edges, surmounted by steel grillage beams, as shown in the diagram of the footing of column 44.

Excepting four columns which are arranged on the arc of a circle around the elevator shafts adjacent to the 66x18-foot light court, all the columns are at the intersections of longitudinal and transverse lines from about 12 to 15 feet apart, but in some cases columns are omitted making maximum spans of nearly 30 feet for the floor girders. The upper sections of the columns are only one story high, all others are two stories, generally 23½ feet high, and all are spliced with horizontal cap plates and standard splice plates, shop-riveted to the lower and field-riveted to the upper sections. The smallest column load is 25,300 pounds, in the twentieth story, where the column is made with two 10-inch channels, latticed. The heaviest loads are, of course, in the basement where one column has a load of 1,194,200 pounds and is built with two 13-inch 50-pound channels, four 16x13/16-inch flange plates and two 12x½-inch web reinforcement plates. Another column has a load of 1,361,400 pounds, which is the maximum, and is built with two 13-inch 50-pound channels, six 16x¾-inch flange cover plates and two 12x¾-inch web reinforcement plates.



Wind Bracing between Columns

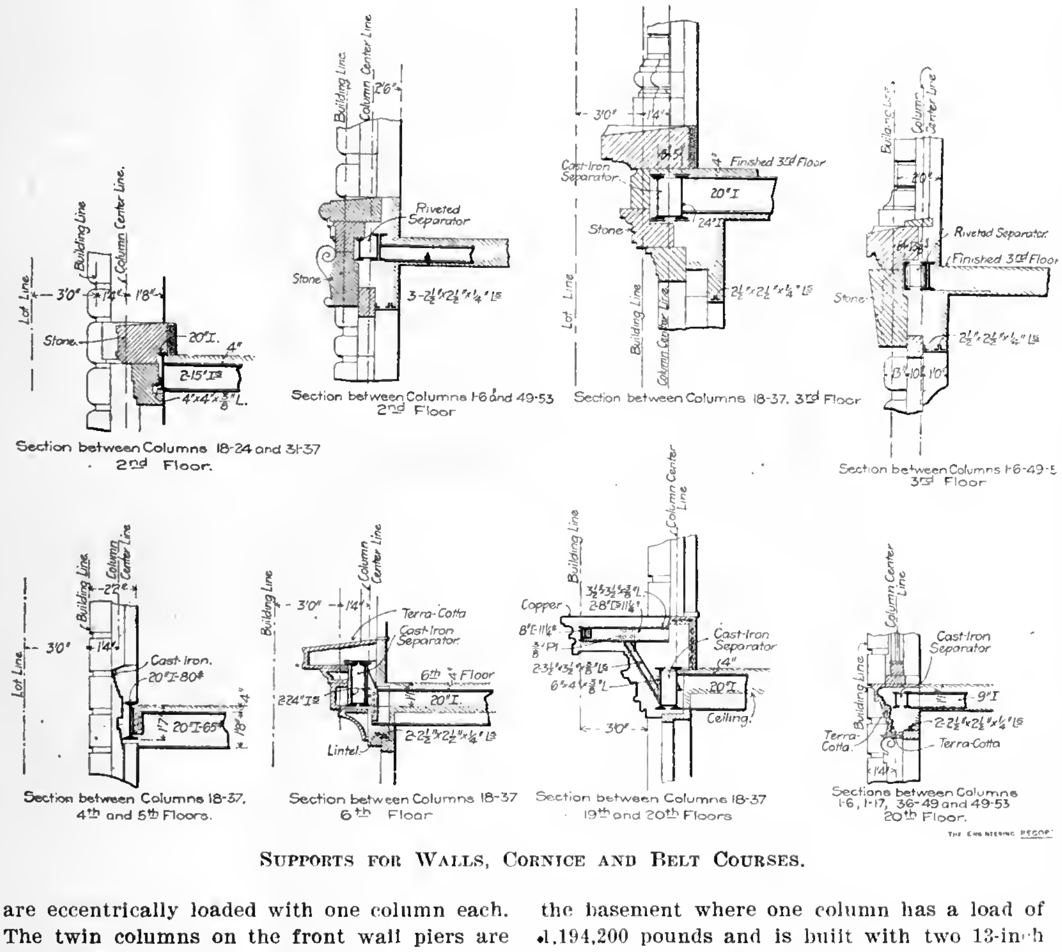
The floors are end-construction hard tile flat arches, calculated for a total load of 160 pounds per square foot and supported on 8, 9 and 10-inch I-beam joists from 4½ to 5½ feet apart and 12 to 15 feet long. They are web-connected to 10 and 12-inch floorbeams of about the same length, or to 20-inch I-beam girders of twice that length. The wall-columns are connected by floorbeams on their center lines; these beams have others of the same size bracketed out from them beyond the faces of the columns, to which they are also riveted, to carry the wall masonry. These beams are 20 inches deep in the long panels and from 9 to 15 inches deep in the shorter panels. The location of columns is shown in the half plan of the building, which gives the arrangement and principal sizes of beams in the tenth to the fourteenth floors inclusive, and is typical of all the floors above the basement. Below the eighth floor the wall girders in the end walls are composed of pairs of 12 and 15-inch channels riveted together, back to back. The framing of the roof



Footing for Column 44.

beams is similar to that of the floors except that some of the beams are lighter and closer together and there are double lines of 20-inch I-beam girders under the walls of a T-shaped steel-frame janitor's house, one story high.

In the lower stories of the Battery Park front the wall stones are notched to rest directly on the top flanges of the wall beams, as shown in the details of the second-floor connections. In the middle panel of the Battery Park front the sixth-floor beams are about 15 inches below the top flanges of the wall columns and their outer ends are connected to the webs of the latter with drop-plates as shown in the detail. In the third-floor tier the wall girders support a very heavy projecting belt course of granite blocks and in the 29 1/3-foot spans of the center panel the wall masonry is supported on a 24-inch 80-pound I-beam which is riveted at the ends to the columns and is connected intermediately to the corresponding floorbeam girder by riveted web diaphragms or separators. The flanges of these 24-inch I-beams are all reinforced by full length 9x¾-inch plates riveted to them, and a continuous horizontal 2½x2½x5/16-inch angle, not shown in the detail, is riveted to the inside of the web of the floor girder to carry the skewbacks of the floor arches. The heaviest projecting course of granite stones is supported directly from the tops of both the wall and floor girders, and two lower courses are secured to them with suspension bars and anchors. In the West Street end of the building the corresponding granite courses are notched over 15-inch channel girders about 15 feet long, which are connected intermediately by vertical transverse diaphragms with a pair of 15-inch channels riveted together, back to back, for the floor girders, and are connected to the columns symmetrically with the wall girders. In the fourth and fifth floors there is a cast-iron moulded fascia plate between the window openings above and below and as no masonry is carried at this level in the middle panel of the building, the wall girder is omitted and the fascia plate is attached to the floor girder as shown in the



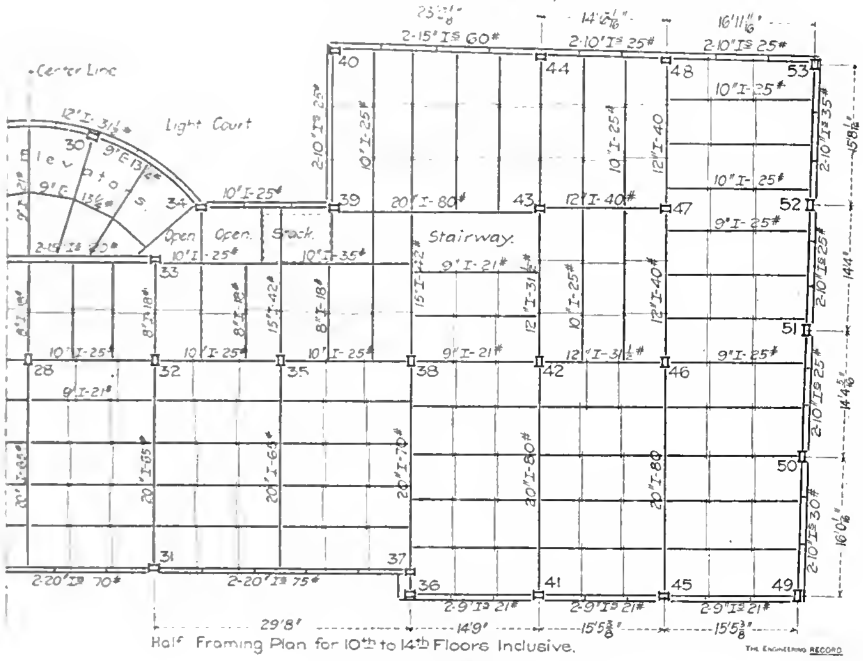
SUPPORTS FOR WALLS, CORNICE AND BELT COURSES.

detail section, which also illustrates the drop end connection for the floorbeams of nearly 21-foot span.

At the nineteenth floor a copper cornice about 4 feet deep projects nearly 4 feet beyond the face of the wall and has light metal cross frames carried by an 8-inch horizontal channel bracketed out from the wall girders and columns, as seen in the cross-section through the middle panel of the Battery Park front. A bracket projects from the face of each column, but as the center columns are nearly 20 feet apart the span is reduced by an intermediate bracket which is similar to the one shown and has the inner end of its two 8-inch horizontal channels built into the wall instead of being riveted to the column web. In the side panels in the front and in the ends of the building, the wall girders are pairs of 8, 9 and 10-inch I-beams, and the knee-brace angles of the cornice brackets are not connected to them at all, but are riveted to the column webs. At the twentieth floor there is no projecting cornice, but there is a course of moulded terra cotta blocks at the height of the wall girders and connected directly to them in the position shown in the section of the floor at the West Street end of the building. In the middle panel of the Battery Park front the arrangement is similar, except that the wall girders are 20 inches deep and are, with the terra cotta course, set back about 28 inches from the building line. The flat roof pitches down towards the Battery Park front and is surmounted by a massive balustrade which, with the outer ends of the roof beams, is carried by wall girders at the upper ends of the columns. On the ends of the building these girders are 12-inch I-beams; in the middle panel of the front they are long-span 20-inch I-beams. In both cases they support the upper edge of the deep copper cornice which projects about 20 inches from the building line and is carried at the lower edge by a pair of I-beams similar to those shown for the lower tiers.

At the two narrow ends of the building transverse wind bracing is provided by a system of knee-braces on all the wall columns up to and including the seventh floor. The wall girders consist in every case of a pair of 12-inch or 15-inch channels riveted together, back to back, on the center line of the row of columns. Between the webs of the channels at each end of each girder there is a vertical ½-inch plate about 2 feet wide which projects 2 feet beyond the upper and lower flanges of the girder as shown in the elevation of one panel of the south wall of the building. Pairs of 3x3-inch flange angles are riveted to all the edges of these plates and serve both to stiffen the diagonal sides and as connections to the columns. These knee-braces only occupy a small space in the panels between the columns and girders and give clearance for large rectangular windows which occupy about one-half the area of the walls. In each end of the building there is a door in the center panel of the first story and to clear it the wall girder is depressed about a foot below the adjacent wall girders, making an irregularity in the braces as shown in the elevation of one panel of the end wall. In all other cases the bracing corresponds to that which is shown for the second floor wall girders.

Mr. H. J. Hardenbergh is the architect of the building and the George A. Fuller Company is the general contractor. The Carnegie Steel Company is the sub-contractor for the 3,000 tons of structural steel in the superstructure, and Messrs. Purdy & Henderson are the consulting engineers.



TYPICAL BEAM PLAN.

The Stability of Chimneys is the subject of regulations issued on April 30 by the Prussian Ministers of Public Works and of Commerce and Manufactures. The stacks must hereafter be designed for a wind pressure of 25½ pounds per square foot, no attention being paid to suction on the lee side and no allowance made for the protection afforded by neighboring structures as a rule. The center of pressure will be taken at the center of gravity of the center vertical cross-section. The pressure on a round stack is to be taken at 67 per cent. of that on a square stack with a face of the same width as the diameter, and at 71 per cent. for an octagonal stack. The same proportions hold for a wind blowing against an angle rather than a face, and this direction is to be assumed in computing the maximum stresses. The horizontal cross-sections must be so planned that in no case will there be a tendency for the joints to open on the windward side farther than an axis through the center of gravity. The allowable pressures are as follows: Ordinary brick laid in a 1:3 lime mortar, 100 pounds per square inch; hard brick in lime and cement mortar, 170 to 210 pounds; concrete simply deposited, 85 to 115 pounds; rammed concrete, 125 to 210 pounds; good earth foundations, 6,000 pounds per square foot, and, in exceptional cases, 8,000 pounds.

Ventilating and Heating the Rochester Athenaeum and Mechanics Institute.

An interesting system of ventilating and heating has been installed in the Rochester Athenaeum and Mechanics Institute, Rochester, New York, embracing hot blast apparatus, indirect steam heating and a considerable amount of direct. There are two large supply fans installed in the basement, the air for which is taken through screened windows, passed through tempering coils and then through a large coke filter. The latter is one of the features of the installation, the economical working of which is enhanced by using for the moistening of the coke the surplus water taken from a Johnson hydraulic air compressor operating in connection with automatic thermostats for temperature regulation throughout the building. From the fans the air is delivered into a plenum chamber, which it leaves through a number of ducts each individually serving a particular part of the structure. Vent ducts are provided for exhaust ventilation and special provision for such is made in the chemical laboratory by having a system of hoods and piping over the tables and using an electric fan to draw the air upward through a flue to the roof. Another interesting feature of the work is a tile duct system under the floor of the basement for the passage of air from the fans to the latter for ventilating purposes. The power house is in an adjoining building and is separated from the Institute by an alley 16 feet wide; the steam piping and electric conduits are carried accross the latter in an underground conduit.

The main structure is three stories high inclusive of the basement, and occupies approximately 44,640 square feet of ground between Plymouth Avenue and Spring Street. The entrance is near the center of the building on Plymouth Avenue and leads into the first floor. There is also an entrance on the Spring Street side as one means of access to the basement from the street. On this floor, as on the floors above, the space is divided into six sections by a main corridor, the smaller halls and a court shown on the basement plan. One of the largest rooms here is the physical culture room, 42x80 feet in size, a fan room, 44x60 feet in plan and 13 feet high, and several others, the dimensions of which may be taken from the accompanying sketch. The first floor contains a library, a public office, three kitchens for cooking classes, four recitation rooms, two laboratories and other rooms for various purposes. The second floor is composed of six rooms for dressmaking classes on the left, biological laboratory, chemical lecture room, rooms for the mechanical department and those for painting, design, etc.

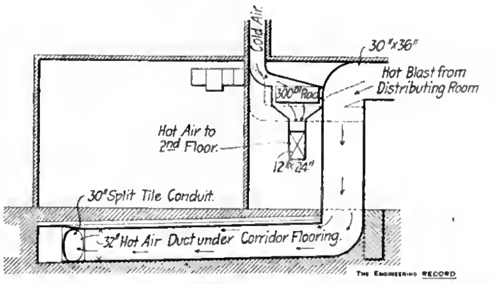
The boiler plant is contained in the narrow building adjacent to the main building. There are three boilers installed, two new ones and one old one. The former are each of 150 horsepower apiece and are of the Cahall vertical water-tube type, 28 feet high and 10 feet 8 inches in diameter. They are fitted with Jones under-feed stokers. The steam pressure usual carried is 60 pounds per square inch. The third boiler is 40 horse-power in capacity, and is of the standard horizontal tubular type made by the Stearns Manufacturing Company, of Erie, Pa. It is set to the side of the others for convenience in piping, a 4-inch pipe being taken from the steam dome in front and carried over to a 5-inch connection from the vertical boilers. From the 5-inch connection, a 7-inch main is led to the other building through the 30-inch conduit running under the alley, and a 5-inch reducing valve introduced in a branch line at a convenient point, so as to obtain a suitable pressure of the steam for heating purposes. A 2½-inch high pressure main is also brought over to the main structure for the fan engine for summer use. A blow-off tank, boiler feed pump, etc., are contained in the old power house, while the location of the auxiliary apparatus for the heating plant of the new building is shown on the basement plan.

Ventilation is accomplished, as mentioned, by the forced blast system. Air is taken into the building through two windows, each 5 feet wide by 10 feet high, covered with ⅜-inch mesh bronzed wire screen and passes on to two tempering coils, one to each window located in the fresh-air room. The tempering coils consist in each case of four sections of 1-inch pipe, one of them with four rows and the other with two rows. The coils were furnished by the B. F. Sturtevant Company, of Boston, and are 7 feet high. In the tempered air chamber there is installed a Johnson humidostat operating automatically, which is controlled from the main office.

The air next comes in contact with the filter, which is constructed of an angle iron frame extending across the room, a distance of 32 feet, supported by standards from the floor and ceiling spaced 2 feet apart and having heavy wire screening of ⅜-inch mesh stretched on either side. Between the screening is a space 9 inches wide which is filled in with broken coke. A horizontal bounding strip on top is a closed water trough, triangular in section, the apex pointing downward and perforated so as to allow such water as is supplied to it for the moistening of the coke to escape slowly and percolate through the latter. At the bottom there is a cement trough constructed to carry off the waste water.

Passing from the filter, the air is drawn into two Sturtevant horizontal steel plate blowers, each with a 9-foot diameter wheel, 4½ feet wide at the periphery, which, when revolving at 150 revolutions per minute, is counted on to deliver 94,000 cubic feet of air per minute against a back-pressure of ⅝ ounce. The fans are rotated on 3 15/16-inch shafting, coupled at the center, with inside bearings and driven by horizontal engines of the same manufacture. The illustration shows the fans and engines. The latter are both 9x12-inch machines. The blowers deliver their air supply to an enclosure in which are placed two heaters having twenty sections of 1-inch pipe, 6 to 14 feet long by 7 feet high, sixteen sections of which have four rows of pipe and four of them two rows. The air thus heated is forced into the plenum chamber shown on the plan.

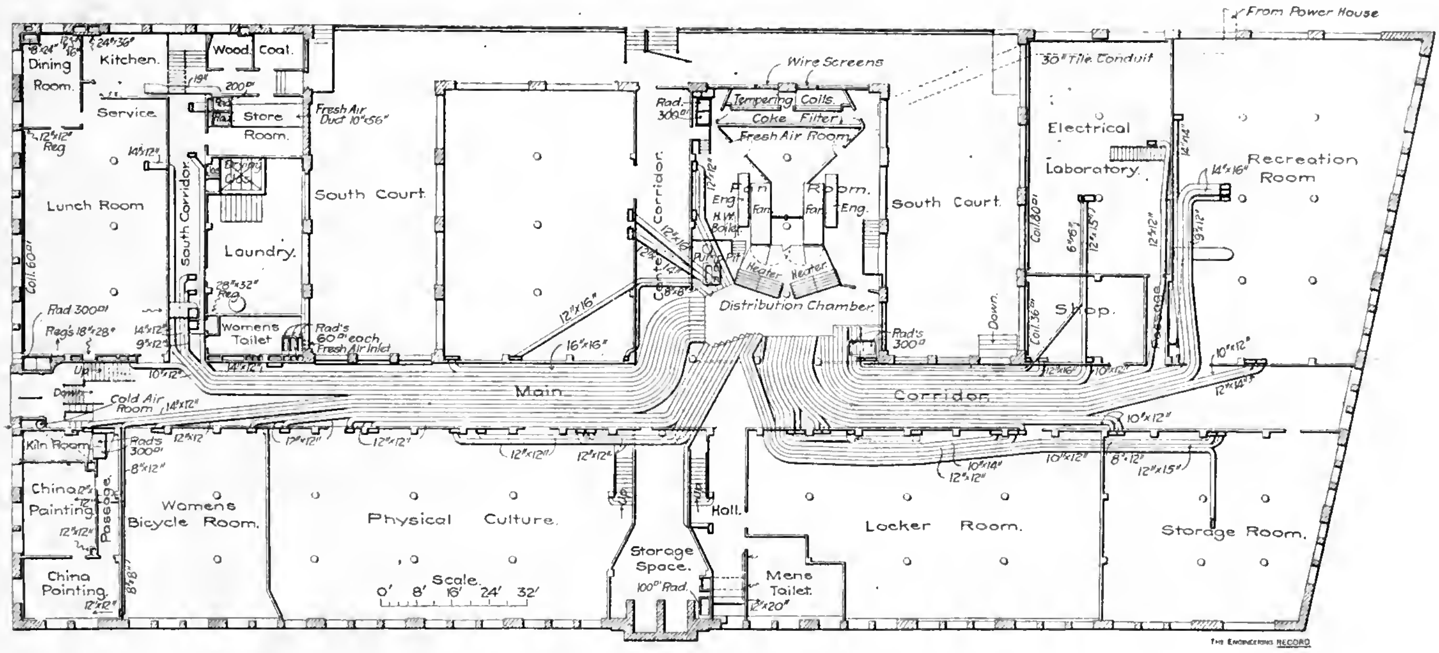
The distribution of warm air is effected as previously mentioned by separate ducts which lead from the distributing chamber to flues individually serving particular portions of the building. In all there are about 50 ducts radiating from this enclosure, the air supply through each being governed by dampers at the mouths, operating automatically under the Johnson system. The accompanying drawings indicate the direction of the ducts and the localities of the flues, the system being so proportioned as to supply a uniform amount of air per minute to each room in proportion to its cubical contents. The tile heat ducts in the basement, extended beneath the floor, consist



ENTRANCE OF BASEMENT DUCT.

of a system of vitrified sewer pipe receiving a supply of warm air through a 30x36-inch vertical brick flue brought from the chamber to a distributing duct, "this duct to be laid in Portland cement mortar and tile drain laid in Portland cement with a water-tight joint." There is also a tile fresh-air duct under the kiln-room floor, taking air from a small room to the left and discharging it over the two indirect radiators shown, the vitiated air passing out through louvres to vent flues. Vent flues throughout the structure have been proportioned about the same as the heat flues, louvres have been set in where necessary, and special provision has been made for the ventilation of the qualitative laboratory by the installment of the system of hoods and piping before mentioned. A small vent duct is also shown in the locker room on the basement floor, and a 10x8-foot stack near the ceiling in the laboratory on the second floor which has a coil of 25 feet of steam pipe with automatic air valves. Wire screening has been used throughout for heat and vent registers. Valves in the vent stacks are closed at night and allow a circulation of the warm air contained in the building.

The auxiliary indirect heating apparatus is set up in various places, the most prominent point being at the basement entrance. In this case there are installed two pin radiators, one above the other and of a total area of 300 square feet on one side of the hall. The fresh air is admitted at a point outside the building wall and allowed to pass under the radiators, thence into the lunch room and to kitchen B, on the floor above. Another example of indirect heating by natural means is that near the center of the main corridor on the basement floor. Here two radiators with a total surface of 300 square feet are set underneath the floor and air is introduced at the court wall, passing out through the registers indicated in the drawings. Another instance is the apparatus under the store room floor taking air from the left-hand court, which, after passing over a pair of radiators set as shown and containing 200 square feet of heating surface, is led to kitchen C above and the store room, etc., below. In a toilet room opening from the south corridor there are three indirect heating stacks installed, of 60 square feet each, which have an air supply through an opening in the court wall. The flues supplied from this heating surface, three in number, are run to the corridors on the two floors above.



BASEMENT, SHOWING HEATING APPARATUS.

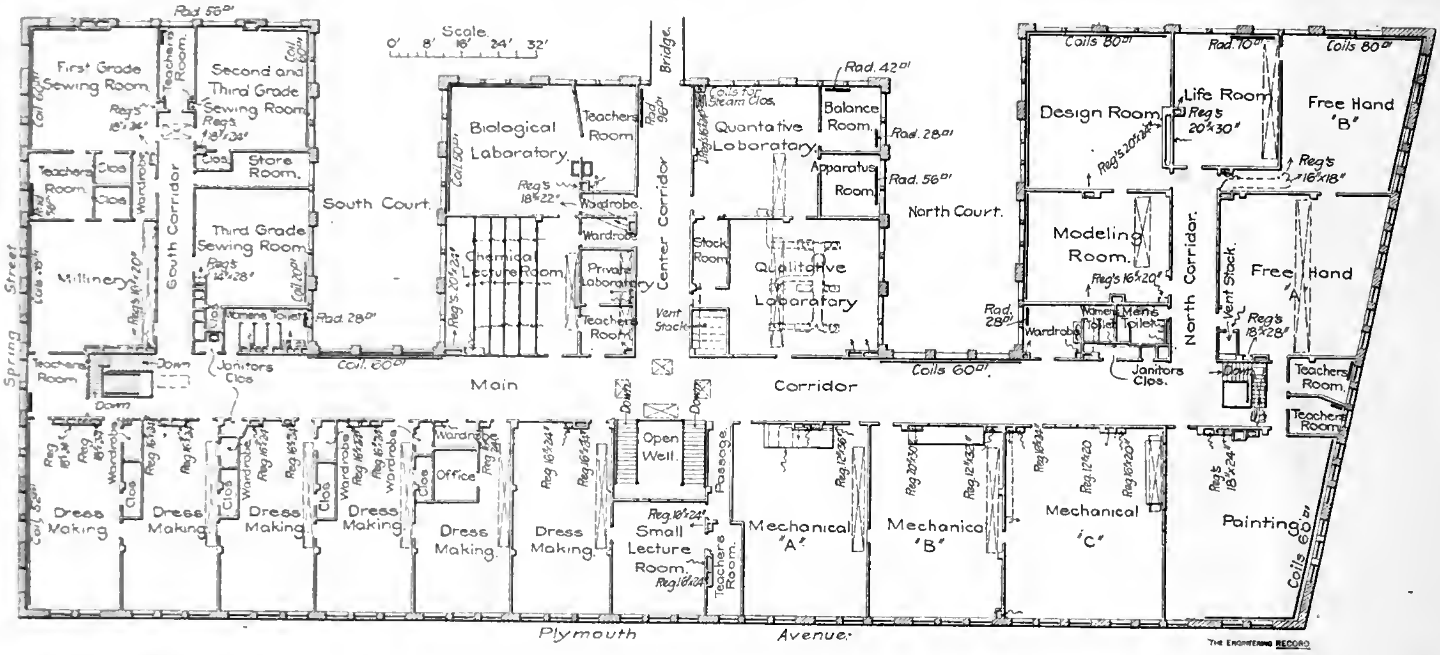
The direct heating of the building is mainly in the offices, teachers' room and kitchen of the first floor. The radiators are of Fowler & Wolfe manufacture. The small offices have each 21 square feet of direct radiation, the board room 84 square feet, and the teacher's room, pantry and kitchen A, 56 square feet apiece. The large lecture room on this floor is heated partly by a coil of 1-inch pipe extending around the room beneath the court windows, and the architectural room and physical laboratory for the study of light, by 60 feet of the same size pipe in each case. Other rooms thus heated on this floor are shown. Several of the rooms on the floor above, which are on the western side, have a similar installation, including the sewing rooms, the biological laboratory, and the fine arts rooms. The window surface of the smaller rooms on the opposite side being small, no heating coils have been necessary to offset the cooling effect.

Steam cooking apparatus is installed in the kitchens and in the drying room steam outlets have been provided, the pressure of the steam being about 60 pounds per square inch for these purposes. In the laundry a complete 9-section metallic drying closet, fitted with large coils for quick drying, was supplied by A. T. Hagan & Company, of Rochester, N. Y.

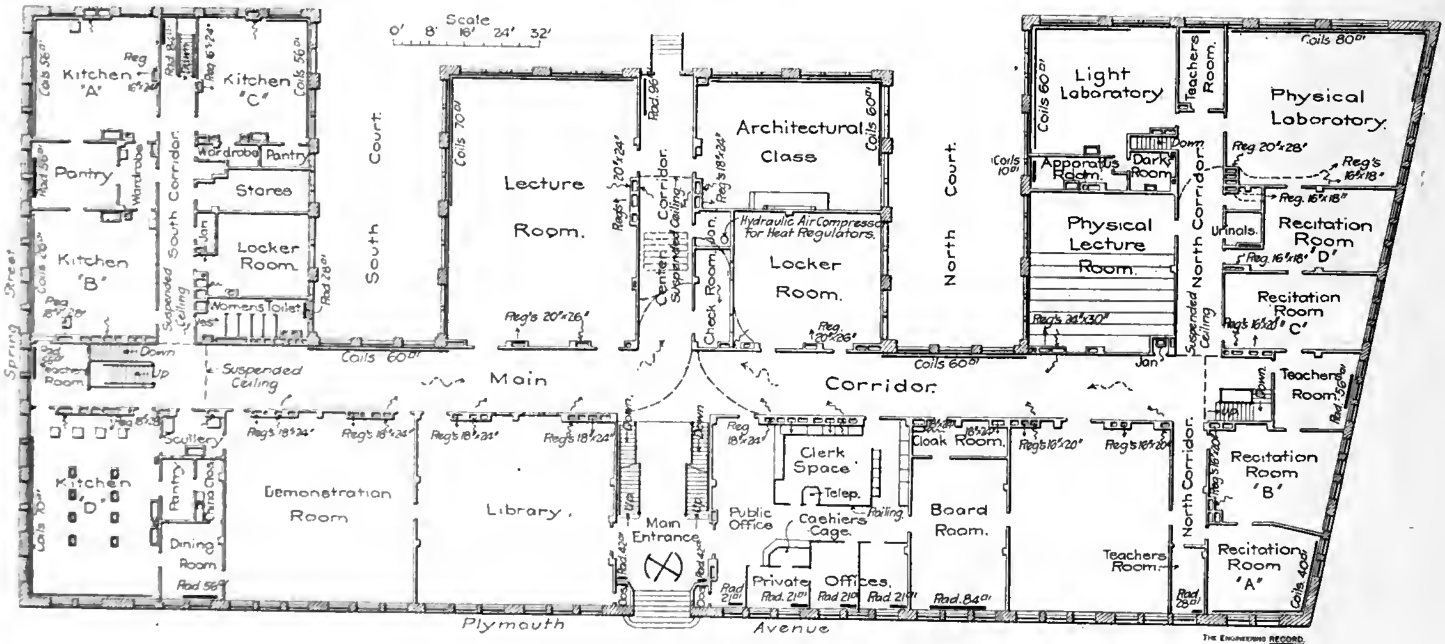
The contract for the heating work required that "the contractor shall guarantee to warm all rooms provided with heat throughout the first and second stories, also the lunch room, dining, kiln and two china painting rooms in the basement to 70 degrees Fahrenheit, and all corridors and the balance of the basement to 60 degrees in zero weather, all at the same time, the temperature to be taken 2 feet above the floor line, with the building constructed with unfurred outside walls and single sash." Regarding the heat ducts and flues, the velocity of warm air in the former has been figured to be about 1,400 feet per minute while that in the latter is probably 600 feet per minute. The Johnson system of temperature regulation is in use on all coils and radiators throughout, as well as the automatic dampers in the air ducts. Valves on all lines are of the Jenkins Brothers manufacture and a 4-inch grease separator of the Baldwin horizontal type is set in the exhaust line from the engines and pumps. Rod and clip hangers are used for supporting all piping, and suitable provision has been made for contraction and expansion of steam lines.

The architect for the building was Mr. J. Foster Warner, of Rochester, New York, who also designed the entire heating apparatus. The contractor having charge of the installation of the warming equipment was Mr. R. T. Ford, also of Rochester. The cost of the entire building and land was $225,000, and was the gift of Mr. George Eastman, of the Eastman Kodak Company, of the same city. The cost of the heating plant including the Cahall boilers was about $30,000.

Pipe Subways at the University of Nebraska, Lincoln, Neb., are described by Mr. G. H. Ellsworth, assistant superintendent of Grounds and Buildings, in the "Blue Print," the annual publication of the Engineering Society of that university. In order to keep the steam mains at a safe distance above water level in the boilers, they had to be carried close to the surface of the ground, requiring a tunnel having a comparatively flat roof. This was built of 3-inch 5½-pound I-beams, bent to a 3-inch camber and spaced 18 inches apart, with the ends resting on the side walls, which are 8 inches thick of hard-burned brick laid in Louisville cement mortar. The roof beams carry 12x18x3-inch porous terra-cotta book tiling having ends notched to slip between the flanges of the beams. On the tile is placed 1:2:4 Louisville cement concrete, 3 inches thick, and a finish coat of 1 inch of Atlas Portland cement mortar, in the proportion of one part cement to two parts sand. The tunnel floor is a brick invert with the bricks laid on edge and grouted with thin cement mortar. With the sandy subsoil underlying the campus, drain tiles were considered unnecessary and were omitted. At each junction box the roof of the tunnel is brought to the surface of the ground and double trap doors, made from ¼-inch steel plate, give access for handling full length pipe to and from the tunnel. Some of the branch lines are carried in smaller tunnels, the roofs of which are of 4-inch flagstones jointed with cement mortar. The return mains are suspended from the steam main hangers by No. 10 galvanized-iron wire cable and were brought to grade by inserting a wooden twister between the wires. Winter temperatures reach 175 degrees Fahrenheit in the main tunnel and little evidence has been found of radiation at the ground surfaces, even where the earth covering is thinnest. During the summer of 1900, 120 feet of concrete tunnel were constructed, with side walls of 1:2:4 Louisville cement concrete, the roof of 1:3:5 Nazareth Portland cement concrete, finishing with 1 inch of 1:2 Portland cement mortar. The walls and roof are 8 inches thick. For supporting the steam mains 1¾x1¾-inch tees are bent to conform to the tunnel roof spaced 12 feet apart with the webs extending slightly inside the arch. Holes in the webs furnish the means for supporting pipe hangers, which consist of pipe rollers suspended from chains.



SECOND FLOOR PLAN.



PLAN OF FIRST FLOOR.

The Drafting System of a British Engine Shop.

So much discussion has taken place of late concerning drafting office methods that considerable interest will doubtless be aroused in a description in "Engineering" of the system of shop drawings adopted by David Rowan & Company, a British engine-building firm. In the drafting office of the company, the drawings are made, with few exceptions, on 40x27-inch sheets. Standard drawings, marked "S. D.," show such arrangements and details as have been adopted as standard articles and which never vary, and may be used for any job without alteration. Contract drawings, or "C.D.," are drawings which have to be made specially for any particular job or contract, and which are peculiar to that job. Alterations or deviations from standard drawings fall under this heading.

Each series of standard and contract drawings has a running number. In order to distinguish between standard and contract drawings a special method of numbering is followed. The standard drawings begin at 1 and run up to 1999, then begin again at 3000 and run up to 3999, and then from 5000 to 5999, and in like manner for higher numbers. The contract drawings begin at 2000 and run up to 2999, then from 4000 to 4999, then from 6000 to 6999, and also in like manner for higher numbers. The drawings are known as "S.D. No. 1890," "C.D. No. 2890," etc., according as they are standard or contract.

The objects of the arrangement are (1) to allow the standard and contract drawings to be kept separately, and (2) yet allow each class to have a continuous series of running numbers, thus avoiding blanks, and showing when a drawing is not in its place in the drawer, and (3) to avoid having two simultaneous series of running numbers.

Each sheet is divided into ten equal rectangles or blocks, measuring 13½ by 8 inches, by dividing its breadth, horizontally, in halves, and its length, vertically, into five parts. Each block or section has a border line drawn ¼ inch from each side, making the space in which the drawing must be contained 13 by 7½ inches. Each block is numbered A, B, C, D, E, F, G, H, and I, and the lower right-hand block is reserved for the drawing number and title.

Each block is known by its symbol, which consists of two letters and a fraction, thus, S.D. 1890/H, the numbers indicating the numbers in the class, and the final letters the particular blocks or sections of the drawings themselves.

In the C. D. series the block devoted to the arrangement occupies section A at the top of the left-hand corner of the sheet, and the details fill the following blocks, each block having one piece, and one only, drawn on it. Should the necessary views of the arrangement or any of its details require more than one block for its proper representation, two adjacent blocks may be taken. Should the drawing require to show the method or attachment of the piece or its relation to another piece, this other piece is to be shown in dotted lines, and will, of course, be drawn in full on another block.

In the S.D. series the same principle is followed; there being but one piece to each block, with the arrangement on block A, and the details following in succeeding blocks.

Immediately a standard or contract drawing is started, the draughtsman goes to the drawing records and books the number, and at the same time he enters the proposed title and his name. On the completion of the drawing he enters particulars of the date finished and full title. The draughtsman immediately fills up a C.D. or S.D. register card for the card cabinet. The standard drawing cards are white and the contract drawing cards are buff colored. These cards give the drawing number, general title, and the sub-title of each block. On the back appears the draughtsman's name, and the date when finished. If the drawing is a contract drawing, the contract number first used is given.

The object of booking a number before the drawing is started is (1) to give the draughtsman a drawing number against which he may charge his time, and (2) to prevent half-finished or delayed drawings from going astray. The drawing after completion is examined by the chief draughtsman, who initials it, and it is passed into the tracing-room for tracing, and the tracing is entered in the drawing record. The tracing being made and having been checked by the chief draughtsman, it is handed back to the draughtsman for him to make his drawing correspond with it. Both are stamped and initialed by the chief draughtsman. The tracing is then passed out for photographing, and the drawing filed away into its drawer in the drawing cabinet, while the register card is filed away in the card cabinet under its section or class of subject in the C.D. or S.D. drawing-register drawer.

Four blue-prints are taken of standard drawings, and are divided as follows: (*a*) Two for works; (*b*) one, of arrangement block only, for rate-fixing department; (*c*) one, of arrangement block only, for drawing office.

The works prints are cut up into the blocks, and each block is pasted on a steel sheet, and is called a "shop card." On the back of each steel sheet is pasted a form, giving the contract numbers which use this particular standard drawing. The shop cards are then varnished over front and back, marked up with the first contract number they are to be used for, dated, and are ready for issuing to the shop. There are thus two sets of shop-cards for shop use, and they are divided as follows:

One complete set, including the "arrangement," is sent to, and is for the exclusive use of, the machine and erecting shops, the machinemen and surface tablemen using the blocks of the details, and the erectors the arrangements. By thus having one piece on one card no two men can require the use of the same card at the same time.

The remaining set is divided between the patternshop and smithy, the sheets containing the cast-iron, cast-brass, or cast-steel details going to the pattern-shop, while those containing forge work go to the smithy, and are for the sole use of these departments. The "arrangements" are sent to either the pattern-shop or smithy as circumstances warrant. To ensure this each card has either "Machine Shop," "Pattern Shop," or "Smithy" stamped on it, so that there can be no doubt subsequently as to the ownership of any shop-card which goes astray. Once these standard shop-cards are issued, they are never returned to the drawing-office unless for alteration or to be cancelled; but always remain in the works, and are stored there in a manner described later on.

The rate-fixing and drawing office sheets (blue-prints *b* and *c*) are next pasted on cardboard sheets. The cards of one set are sent down to the rate-fixing department, and are called "time-office cards." The cards of the other set are filed away in the drawing-office for use there. These are called "drawing-office cards." The drawing-office set of cards is used for registering (on their backs) the contract or engine numbers which have used these particular blocks in their construction, and thus avoid stamping the drawings themselves. The time-office cards also have on their backs the contract numbers, although this is not essential. They were principally used as a guide for determining the time allowances for each operation under the premium system of payment followed at these works, when this system was started and before sufficient data had been accumulated. The cards are now only used for reference.

When contract drawings have to be issued, only three blue prints are taken—one on cloth and two on paper—and are distributed as follows: (*a*) One, cloth, for machine shop; (*b*) one, paper, for pattern shop and smithy; (*c*) one, paper, of arrangement only, for rate-fixing department.

These are cut up, and each set for each department is clipped together with a title-page on the outside. The machine-shop gets a complete cloth set. The second set is divided between the smithy and pattern-shop. The photoprint of the arrangement is sent to the rate-fixing department. As each of these contract drawing blocks has the contract or engine number stamped on its face, as well as its own C.D. number, it may become detached from the rest, and yet not be lost or separated from its contract number. Unlike the standard drawings, these contract drawings are returned to the drawing-office on completion of the job, and are either destroyed or kept for the re-issue of a duplicate job.

The machine-shop set of standard drawings is stored and kept in the machine-shop toolroom in trays, the drawings being in their proper numerical order. The storeman, who has charge of them, hands them out to whoever requires them, at the same time marking on the slip provided for the purpose the man's number and date. As they are returned this entry is scored off. The contract drawings are treated in the same manner. The pattern-shop and smithy sets of drawings are kept in their respective department in trays, as in the machine-shop.

Each department has thus a complete set of drawings for its own exclusive use, and does not require to borrow.

As the drawings themselves are not regarded as shop orders to proceed with the work, but merely as guides to show how the work is to be done; and especially as the standard shop-cards always remain in the works, never returning to the drawing-office, some sort of order to the shops is required to indicate which shop-cards are to be used for a particular contract. Cards, 6 by 4 inches, called "factory orders," are therefore issued, and for uniformity as well as for indexing purposes, these are issued with the contract drawings. One card is issued for each block or section to be used; in other words, there is one card for each piece and arrangement of pieces. One set of these factory orders is written out, and after being entered in the drawing register, is issued to the works. These factory orders are subdivided into two classes as under: 1, factory orders for material ordered from inside; 2, factory orders for material ordered from outside.

The factory orders are still further subdivided in the drawing-office into:

(*a*) Those referring to general arrangements which are sent down to the works manager's office direct.

(*b*) Those referring to cast details are sent direct into the pattern-shop.

(*c*) Those referring to malleable iron details, which are sent direct into the smithy.

Those factory orders (*a*) dealing with arrangements of details are sent down to the engine-works manager's office in order to keep him advised that the material called for on the arrangement factory order has been ordered from the various departments. These factory orders remain in his office until the termination of the contract.

Factory orders (*b*) and (*c*) are sent to the pattern-shop or the smithy; the foreman, or his clerk, of each department files these orders in the special drawer in the compartment, or division, set apart for the contract number. After the foreman of each department has executed the work called for on the factory order, he takes the order from its place, and, having initialed and dated it on the back, in a space set apart for the purpose, he sends it into the machine-shop, where it is placed in a cabinet, which has drawers divided into compartments set apart for particular contract numbers. Thus the foreman pattern-maker and foreman smith, by looking over the factory orders, see only the work which is ahead of them, and which has yet to be done for each particular contract number. As each factory order represents only one kind of article, it follows that so long as there are any lying in the compartment for any particular contract number, the pieces called for on these factory orders have yet to be made. Thus the risk of forgetting small details is avoided, or, at least, very much minimized.

The factory orders for the material which is not made in the works, but is to be ordered from outside contractors, are sent direct from the drawing-office to the counting-house with photo-prints, or sketches, of the material which they represent. If only a sketch is supplied, this is made on the ordinary foolscap sheet, and sent with the factory order. This sketch is copied into the drawing-office copy-book, set apart for this purpose, and it, as well as the factory order-card, has the copy-book number and page marked on its top right-hand corner. These factory orders for outside material are placed by themselves in the counting-house in a receptacle under the charge of the order clerk, who initials and dates them as each order is sent to the outside contractors. He will send them down to the works, distributing them as follows: Those factory orders calling for material or goods of the nature of finished material (such as asbestos, cocks, rubber valves and safety valves), which should be delivered into store, are sent down to the storemen, and are filed by them in a suitable cabinet drawer under their contract numbers. The storemen will thus be kept advised of the ordering of this material and by referring to the factory orders in the store the manager and foremen know what has been ordered, and when it was ordered. By suitable filing they are able to say what is delivered and what has still to be delivered.

Those factory orders dealing with raw material ordered direct from outside people, and upon which machine work has to be done (such as forgings of shafting, connecting-rods, etc.) are sent down to the machine-shop, and there filed in the cabinet drawer amongst the other factory orders from the smithy and pattern-shop.

As the factory orders from the pattern-shop, smithy, and some from the counting house all converge in the machine-shop, they have to be available for the inspection of the various foremen who have to deal with them. It is obvious from the foregoing arrangement that only the smithy factory orders represent pieces actually made and delivered to the machine-shop, and that when these factory orders reach the machine-shop the pieces called for are actually in existence and awaiting the machine work. This, however, is not the case with the factory orders which are sent in from the pattern-shop and counting-house. When these cards reach the machine-shop they only inform that department that these pieces have been ordered and when they have been ordered; but as to whether the pieces are delivered, or are to be delivered, no definite information is given. This want has to be submitted to for the present, although it might be remedied in one or other of the following methods: (1) By making the man who receives the castings and heavy forgings retain possession of the factory orders until the actual pieces are delivered, when he could then place them in the machine-shop cabinet; or (2) by retaining the factory orders in the pattern-shop and counting-house until the pieces were delivered, and then sending them down to the machine-shop.

The factory order cards for valve chests and cocks made at the works are white. They are used for ordering out all valves, chests, and cocks, etc., and other material in connection with the pipe arrangements. One valve or article only is sketched on each card, with all other necessary information in copying ink. These factory orders are reproduced in the mimeograph machine, and the copy is sent to the pattern-shop and smithy as required, and filed under the proper contract number until the valve or piece has been ordered. The foreman then initials and dates the card, and sends it down to the machine-shop, where it is filed until that department's machine work has been done on it. It is then initialed and dated by the foreman, sent up to the erecting-shop foreman, and filed by him in such a manner as to show what has been finished and is ready, and what yet remains to be done. The original set is retained in the drawing-office.

In addition to the above mimeograph copy, and at the same time as it is being taken, four copies on a foolscap sheet are taken for the use of the outside foreman and erecting-shop foreman. There is also one spare and one for the engine-works manager.

The factory orders from smithy, pattern-shop, and counting-house, duly initialed and dated, showing that they have had the attention of these departments, are then sent down to the machine-shop, to be placed in the cabinet which is in the tool-room, being deposited in the drawer for factory orders and in the compartment for the contract number. Each of the compartments is still further subdivided by means of guide-cards into sections for A shop; B shop; D and E shops, and finishing shop. It is the duty of the engine-works manager to allocate these factory cards to the proper sections by placing them in each of their compartments. Thus by inspection of the cabinet at any time will be seen how much work for each department is waiting to be done. Those factory orders remain in the cabinet drawer until all machine work is completed, when they will be removed and placed in the compartment for finished work.

A Break in a 36-inch Water Main is described in the annual report of Superintendent R. C. P. Coggeshall, of the New Bedford, Mass., Water Board, from which the following account is taken: The break was caused by the blowing out of a large piece in the middle of the pipe, which was of cast iron. It approached an oval in shape, 3 feet wide and 5 feet long, and the piece came out very much as a cover is lifted off of a stove, there being no cracks in the remainder of the pipe. The break extended from the bottom of the pipe upward upon the side, and as far as could be seen the iron was of full thickness and of good quality. No satisfactory explanation of the break could be offered on the ground of water hammer or defects.

Trade Publications.

The Fort Wayne Electric Works, Fort Wayne, Ind., have issued a bulletin describing the leading features of their direct-connected type of direct-current generators, which are made with capacities of 20 to 800 kilowatts at 125, 250 and 575 volts.

The Richmond Stove Co., 2 Square de l'Opera, Paris, has issued a well-illustrated catalogue in French describing its line of low-pressure steam and hot-water heaters. The cuts are evidently the work of American engravers, but all dimensions and other technical data are in the metric system.

The Pierce, Butler & Pierce Mfg. Co., Syracuse, has issued a well-illustrated book of tables of the sizes, capacities and prices of its heating apparatus, which embraces seven types of steam boilers, nine types of hot water boilers, three types of tank heaters and numerous styles of direct and indirect radiators.

The lighting of the underground stations of the Rapid Transit Railway in New York will be largely done by means of steel-concrete vault lights of a type described in this journal on Sept. 7, 1901. A description of the system and an account of some tests made with it by Mr. William Barclay Parsons are given in a circular from the makers, Tucker & Vinton, 156 Fifth Ave., New York.

Makers of concrete in sufficient quantities to warrant the use of power mixers will find some interesting comments on such plant in Circular A of the Ransome Concrete Machinery Co., 11 Broadway, New York. For many years Mr. E. L. Ransome has been building concrete work in all parts of the country, and has devised various appliances for his work. The mixer described in Circular A was used by him for many years before being manufactured for general sale, and its record covers work from the Atlantic to the Pacific.

The American Steel & Wire Co., Chicago, has prepared a series of tables on wire for electric purposes giving (a) dimensions and weights of pure copper wire, (b) comparative sizes of various gauges, (c) comparative weights of copper wire of the same numbers of different gauges, (d) weights per mile of copper wire by different gauges, (e) resistance of pure annealed copper wire, (f) standard copper conductors, (g) weights of standard copper cables, bare and weatherproof. There are also a number of other tables on iron and steel wire, cables and other wire products.

A 208-page book concerning carts, pumps, chains, concrete plant, derricks and their fittings, cars, hoisting and other engines, hand and horse powers, plows, cranes, dredges and other plant useful to the general contractor has been prepared by the Dobbie Foundry and Machine Co., Niagara Falls, N. Y. It is fully illustrated and is particularly explicit in the section relating to derricks.

A small catalogue of air compressors, both steam-actuated and belt-driven, and vertical and horizontal receivers, has been issued by the Herron & Bury Mfg. Co., Erie, Pa. Illustrations and tables of sizes are given; but as the company believes it can best explain the details of construction by correspondence, nothing of the sort is attempted.

A well-printed description of the Acme type of fire-box boilers for heating purposes has been prepared by the American Radiator Co., Chicago. It shows the construction, explains the setting, and gives useful hints on the construction of chimneys. The same company has also brought out a twelfth edition of "The Homes Successful," a gospel of good heating, published in a form that is the acme of tasteful typography.

A 140-page general catalogue of pumping machinery, which has been issued by the Stilwell-Bierce & Smith-Valle Co., Dayton, is a sort of encyclopædia of the subject. It gives a great number of engravings of various types of pumps, from the diaphragm pattern to the high-duty engine for water-works, with brief notes on the service for which each type is best suited. There are also many useful hydraulic tables and several pages of suggestions for setting and connecting pumps.

Personal and Obituary Notes.

Capt. Robert McGregor, Corps of Engineers, U. S. A., has been ordered to report to the acting civil governor of the Philippine Islands for assignment as engineer for the city of Manila.

Mr. Arthur M. Greene, Jr., instructor in mechanical engineering at the University of Pennsylvania, has accepted the chair of mechanical engineering at the University of Missouri, Columbia, Mo.

Mr. Charles M. Mills, M. Am. Soc. C. E., has resigned his position as assistant engineer in the Bureau of Surveys of Philadelphia to accept a post as principal assistant engineer in charge of subway and elevated road work for the Philadelphia Rapid Transit Company.

Col. Alexander Mackenzie, Major Harry F. Hodges and Captains Edward Burr, Charles H. McKinstrey and William V. Judson, Corps of Engineers, have been appointed a board to review all new projects for improvements under the provisions of the river and harbor bill recently passed by Congress.

Charles C. Gilman, of Marshalltown, Ia., died in Chicago July 10. He was at one time chief engineer of the Iowa Central Railway and later of the Wisconsin, Iowa & Nebraska railroad, now the Chicago Great Western. During the past 25 years he has been engaged largely in railway contracting and at the time of his death was completing work for the Baltimore & Ohio Railroad. He built two sections of the Chicago drainage canal.

Although in his article elsewhere in this issue on the power plant of the Pike's Peak Power Co., Capt. R. M. Jones does not mention that he was responsible for all the engineering work involved, such was nevertheless the fact. The construction of the plant presented obstacles which would appear practically insurmountable to many engineers without his experience in difficult work in the Rocky Mountain region. He was the engineer of the Big Cottonwood and Jordan Narrows plants in the Great Salt Lake valley and prior to that was engaged on both lighting and street railway systems in numerous cities in the region named.

The resignation of Adin Mann as city engineer of Elgin, Ill., again calls attention to the fact that the Nestor of steam engineering is still in active practice. Mr. Mann is 86 years of age, but Charles H. Haswell, who is in charge of New York City work on Riker Island, will be 94 years old in a few months. In 1837 he was chief engineer of the only steam vessel in the U. S. navy, in 1843 he was engineer-in-chief of that department, in 1844 he published the first edition of his famous "Pocket-Book," and in 1847-48 designed the boilers and engines of the U. S. steam frigate "Powhatan," one of the most successful vessels of the time. His book entitled "Reminiscences of an Octogenarian of the City of New York" is replete with information of interest to all who care to study municipal conditions and phases of life before the Civil War.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages 72, xv, xviii and xxvii.

WATER.

Whatcom, Wash.—City Clk. W. H. Hildebrand writes that the City Council will receive bids on Aug. 18 for approximately 565 tons of cast-iron water main, 16-in. in diameter; also bids for laying same, either in one contract or separate contracts. E. C. Lyle, Engr. in Charge. Estimated cost of improvement, $30,000.

Manning, Ia.—Prof. A. Marston, Ames, Ia., is designing a 60,000-gal. steel water tower 100 ft. high.

Sacramento, Cal.—C. M. Phinney, City Engr's Office, writes that on June 16 a contract was awarded to Henry R. Worthington for a 2,000,000-gal. pump, to be installed at the water works, to be considered an emergency pump until such time as a new water supply can be secured.

Gloucester, Mass.—H. W. Spooner, Engr. Bd. of Water Comrs., writes that bids, opened July 7, for the construction of a dam and all appurtenances thereto, will not be made public, according to a vote of the Comrs.; the contract was awarded June 10 to Coleman Bros., of Everett, Mass.

Pickens, Miss.—Water works bonds to the amount of $6,000 will be sold Aug. 1. J. F. Wilburn, Town Clk. Plans for the water works system are being prepared by Kirkpatrick & Johnson, of Jackson, Miss.

Biloxi, Miss.—Kirkpatrick & Johnson, of Jackson, Miss., have been engaged to prepare plans for a water works system, supply to be from artesian wells, with elevated tank, pumping to be done by the head for the wells.

Dunn, N. C.—Engr. in Charge John W. Hays, of Petersburg, Va., writes that water works and an electric light plant are to be built by day labor; cost, $35,000.

South Omaha, Neb.—The City Council has granted the Omaha Water Co. an extension of its franchise from Oct., 1904, to Oct., 1914.

Greeley, Colo.—The Poudre Valley Reservoir Co. is of Greeley, is reported to have been incorporated by A. H. Myers, Thos. Smith, W. R. Clark and others; capital, $250,000.

Brandon, Manitoba.—A recommendation has been passed by the City Council for the removal of the pumping station to higher ground and for the increase of the present pumping plant by the addition of 2 pumps of 1,000,000 imperial gal. each, to be operated by electric power; a standpipe or water tower; new intake and filtering galleries, and the construction of new pumping station. The power will be supplied by the Brandon Electric Light Co. from the company's water power plant on Saskatchewan River. W. H. Shillinglaw, City Engr.

Ivanhoe, Minn.—Engrs. Loweth & Wolff, St. Paul, write that the contract for constructing water works has been awarded to the Des Moines Bridge & Iron Co., Des Moines, Ia., at $8,780.

Baton Rouge, La.—Local press reports state that the City Council Com. on Water has determined to secure the services of Freeman C. Coffin, of Boston, Mass., to examine the plant, mains and all property of the local water company, with a view to fixing its value and establishing a basis for negotiations for its purchase, or for the erection of a water works system by the city.

Wheeling, W. Va.—The Council Com. on Water & Fire, the Fire Underwriter and the Water Bd. have recommended to the Council an additional storage reservoir having a capacity of 20,000,000 gal.; also additional fire hydrants.

Clinton, Ia.—Press reports state that a company is being organized to construct a canal down the east side of the Mississippi River, from Clinton, Ia., to near Lyndon, Ill.

Meridian, Miss.—This city has purchased 15 acres of land on Mount Barton, 1 mile south of the city on which to construct a reservoir for the proposed independent gravity water works system; deep well pumps to supply the water for the reservoir. An election will probably soon be held to vote on the issue of $200,000 bonds for said system.

Great Falls, Mont.—Bids are wanted July 28 for $45,000 water bonds. W. H. Smith, City Clk.

Bird Island, Minn.—Bids are wanted July 22 for constructing an 8-in. tubular well; also at the same time for constructing a complete system of water works. Frank Murray, Village Recorder.

Gibbon, Minn.—Bids are wanted July 25 for constructing a system of water works from plans by Oscar Claussen, Engr., St. Paul.

Eden Valley, Minn.—W. R. Salisbury, Village Recorder, will receive bids July 26 for the construction of a water works plant.

Milwaukee, Wis.—Bids are wanted Sept. 5 for furnishing and erecting at High Service Pumping Station, North Ave. and 10th St., one 8,000,000-gal. pumping engine and one horizontal tubular boiler. Bids are also wanted July 21 for furnishing such corporation stop-cocks as may be required by the Water Dept. during 1902. Chas. J. Poetsch, Comr. of Pub. Wks.

Summit, N. J.—A Com. of the Council is investigating the question of municipal ownership of water and light franchises.

Cleveland, O.—See "Sewerage and Sewage Disposal."

Lorain, O.—City Engr. Chas. S. Ferguson writes that it is proposed to improve the water works at a probable cost of $32,000. C. L. Penney, Supt.

Rockville, Md.—The Town Council has decided to drill an additional artesian well.

Grinnell, Ia.—D. W. Morris, of the Grinnell Water Co. writes that said company, recently incorporated with a capital of $25,000, proposes to construct a dam with a watershed of 1,000 acres, lay mains, erect standpipe and pumping station. Plans have not yet been made. H. W. Spaulding, Pres. of Co.

Loveland, Colo.—Local press reports state that Lowell C. Lloyd is interested in the Boyd Lake Irrigation Co., which has been organized with a capital of $250,000.

Milford, Ind.—Bids will be received by the Milford Water Co., at Miles & Higbee's Bank, Milford, until July 24 for the construction of water works.

Staunton, Va.—S. M. Gray, Providence, R. I., has been retained to advise this city in regard to obtaining a new water supply; the water to be brought by gravity from the mountains, some 15 miles distant.

Avon, N. J.—Mayor John Thomson writes that proposed water works and sewerage systems will probably cost about $65,000. Halsey & Logan, 163 Market St., Newark, Engrs. in Charge. Francis Collingwood, Elizabeth, N. J., Consulting Engr.

Kenmore, N. J.—According to local press reports the village authorities have signed a contract with the Depew & Lake Erie Water Co. This company will be shortly merged with the Western New York Water Co. It is stated that the water for Kenmore will be brought in 12-in. mains from Depew, a distance of 14 miles, at a cost of $140,000.

Cincinnati, O.—Local press reports state that the Comrs. of Water Works have awarded the contract for buildings, foundations and drains for the Eastern Pumping Station to the U. S. Const. Co., of Milwaukee, Wis., for $183,231.

Springfield, Ill.—In his report to the Council, Consulting Engr. Daniel W. Mead, of Chicago, recommends the following improvements for the water works: dam, estimated to cost $6,600; sedimentation basin, $14,700; 6,000,000-gal. filter, $60,000; clear water basin, $13,000; other expenses at $9,430, making a total of $103,730.

Muskogee, Ind. Ter.—Bids are wanted July 23 for furnishing material and constructing water works and a sewerage system. Bids will be received for the whole or portions of the work as follows: Building tunnel or pipe line under Arkansas River, 2,500 ft. in length; distribution system, including 10 miles of pipe, power plant, etc.; standpipe, 120x25 ft.; sewer system; two 1,500,000-gal. pumps, cast-iron pipe, etc.

Yonkers, N. Y.—Bids will be received by the Bd. Water Comrs., Aug. 7, for a horizontal, high-duty, compound condensing, duplex, direct-acting pump, having a capacity of 8,000,000 U. S. gals. in 24 hours, at the Low Service pumping station, as advertised in the Engineering Record. Bids are wanted July 7 for 335 lengths of 24-in. pipe at 2,811 lbs. per length of 12 ft., and 20 tons of special castings. Jos. H. Beall, Pres. Bd. Water Comrs.

Bolivar, N. Y.—It is stated that the Village Bd. will receive bids July 25 for the purchase of the water works.

Wellsburg, W. Va.—It is stated that bids are wanted July 26 for a reservoir, water mains and valves. M. E. Boyd, Engr.; Jas. N. Beard, Chmn. Water Bd.

Philadelphia, Pa.—The Common Council has passed the bill creating a temporary bureau for the improvement, extension and filtration of the water supply, to co-operate with and form an adjunct to the Bureau of Water; the bill appropriates $500,000 for the purpose of carrying out the ordinance's terms.

Worcester, Mass.—The City Council on July 14 adopted an order for laying water pipe in Quinsigamond Ave.; estimated cost, $22,386.

Troy, N. Y.—Water works bonds to the amount of $400,000 have been sold.

Springdale, Ark.—Bids will be received Aug. 1 by the Water Wks. Comn. for the construction of water works. C. J. Chapman, Secy.

Yardley, Pa.—Bids will be received Aug. 5 by T. S. Cadwallader, Pres. Yardley Water & Power Co., for cast-iron pipes and appurtenances, laying pipe lines and erecting standpipe, 10x50; about 179 lengths 8-in. pipe, 510 lbs. per length; 339 lengths 6-in. pipe, 346 lbs. per length; 386 lengths 4-in. pipe, 208 lbs. per length; 5 tons specials, etc., will be required.

Warrington, W. Va.—Bids are wanted July 23 for 3,900 ft. 10, 8, 6 and 4-in. cast-iron pipe, cast-iron gates, hydrants, etc. B. E. Mitchell, Chmn. Water Com.

Lewiston, N. Y.—The Lower Niagara River Power & Water Supply Co., of Lewiston, is reported to have been incorporated, with a capital of $5,000,000. Directors: Jas. Low, Jas. S. Simmons and F. J. Brown, of Niagara Falls.

Battle Creek, Mich.—The Bd. of Works has appointed a Com. to look into the matter of installing a filter for the water supply. Probable cost, $30,000.

Buffalo, N. Y.—Local press reports state that the Western New York Water Co. has been mortgaged to the amount of $10,000,000 for proposed improvements. Wm. B. Cutter, Pres.

Richfield, Utah.—The City Council has voted to levy a tax of 1 per cent. for the construction of water works, estimated to cost $18,000.

Columbus, O.—The City Sinking Fund Comrs. are stated to have sold $102,000 Scioto River dam bonds.

Covington, Tenn.—J. A. Omberg, Jr., of Memphis, employed by the town as an expert to estimate the value of the plant of the water works company, estimates the value of said plant at $10,333.

St. Ansgar, Ia.—Bids are wanted July 22 for constructing water works. C. T. Tollefson, Town Clk.

Niles, O.—City Engr. Wm. Wilson writes that the Water Wks. Trus., S. F. Bycraft, Pres., will receive bids Aug. 14 for a well 25 ft. in diameter. Probable cost, $5,000.

Milton, Mass.—At a recent town meeting it was voted to purchase the property and rights of the Milton Water Co. for $315,000.

Avon, S. D.—Press reports state that a system of water works to cost $5,000 will be put in as soon as a water supply is assured.

Worthington, Minn.—The Council contemplates improvements to the water works and electric light plant.

Wickford, R. I.—The Town Council has granted to Thos. F. McDonnell and J. H. Sheed, representing the Wickford Light & Water Co., a franchise for laying water pipes in all streets of the town.

Ruthton, Minn.—At a recent special election it was voted to build a system of water works.

Providence, R. I.—Local press reports state that the contract for constructing the slow sand filtration plant has been awarded to Edw. W. Everson and Fred. E. Shaw, both of Providence. Their joint bid is said to be within the $225,000 appropriation.

Monessen, Pa.—Local press reports state that Burns & Martin are preparing to make improvements that will cost about $1,000,000. Among the improvements contemplated, there will be a water works system.

La Junta, Colo.—The City Council is considering plans for improving the water works.

Hartwell, Ga.—The municipal authorities have decided to erect as soon as practicable water works and an electric light plant. W. T. Johnson, Mayor.

Waynesboro, Pa.—The directors of the Waynesboro Water Co. have determined upon improvements, including the construction of a dam, sluiceway and reservoir.

Zanesville, O.—Local press reports state that the Water Works Trus. propose to bore 20 wells for an increased water supply. Probable cost, $35,000.

Columbia, Pa.—The stockholders of the Columbia Water Co. have authorized an increase of the capital stock from $100,000 to $300,000. Part of this sum to be used for the installation of a filtration plant.

Columbus, Ind.—Local press reports state that a contract is about to be let by the City Council for a new pump with 5,000,000 gal. capacity.

Manchester, Va.—The City Council has appointed J. T. Abbott and A. R. Hooker as a committee to consider some plan for purifying the present system of water works or getting clear water in some manner.

Denver, Colo.—F. F. Noxon, of Colorado Springs, has made a proposition to the city to deed to the city Tarryall Creek reservoir site, 54 miles from Denver. In return for the grant he asks that the city give him the exclusive right to use the water for power purposes between the dam and Deansbury. The cost of the dam to collect the water and of other expenses in connection with the construction of the reservoir, and of flumes and pipe lines to Deansbury, is estimated at $1,800,000.

Bedford, Wis.—The proposition to issue $100,000 bonds for the construction of water mains in the business section of the city carried at the recent election.

SEWERAGE AND SEWAGE DISPOSAL.

Grinnell, Ia.—Prof. A. Marston, Ames, Ia., has designed a 250,000-gal. septic tank system.

City Clk. J. F. Wilson writes that the sewer system is to be extended; work to include 4,000 ft. of 8-in. sewer pipe, 4,000 ft. of 8-in. water pipe, 15,000 vitrified bricks, 5 flush tanks and 3 manholes. J. C. Goodrich, Supt. of Sewers.

Depew, N. Y.—Bids will be received on July 21 by the Village Trus. for labor and material for the construction of a lateral sewer in Ellicott Road. J. C. Glade, Village Clk.

Philadelphia, Pa.—Bids are wanted July 23 for the construction of main and branch sewers, inlets, manholes, laterals, etc.; total estimated cost, $435,000. Wm. C. Haddock, Dir. Dept. Pub. Wks.

Pittsburg, Pa.—Bids are wanted July 23 for constructing a 15-in. pipe sewer on Olney Alley, Orion and Ajax Sts., also for culvert under Oakwood St. J. O. Brown, City Recorder.

Richmond, N. Y.—Bids are wanted July 25 for furnishing all labor and material required for completing a system of sewers in the former village of Tottenville; the engineer's estimate of quantities includes 7,800 ft. of 8-in. vit. pipe laid, 13 flush tanks with siphons, etc. Geo. Cromwell, Pres. Boro. of Richmond, New York City.

Rhinebeck, N. Y.—Bids are wanted July 21 for the construction of a storm water sewer and appurtenances. A. Lee Wager, Pres. Village Trus.

Oneida, N. Y.—A press report states that bids will be received by the Bd. Pub. Wks., July 28, for the construction of vitrified stoneware sewers in 6 streets.

Chester, Pa.—Bids are wanted July 21 for the construction of sewers in 7 streets. Wm. M. Boulden, Chmn. Com. on Sewers.

Cleveland, O.—Bids are wanted Aug. 11 for the purchase of $65,000 sewer bonds, $100,000 water bonds, $100,000 elevated roadway bonds, and $30,000 Walworth Run bridge bonds. J. P. Madigan, City Aud.

Opelousas, La.—Ira W. Sylvester, City Engr., Alexandria, La., has been employed to prepare plans and estimates for the proposed sewer system.

Wapakoneta, O.—Bids are wanted July 28 for improving Water St. by the construction of a main sewer, with connections, etc. Chas. E. Fisher, Village Clk.

Appleton, Wis.—City Clk. A. E. Heideman will receive bids until Aug. 6 for the construction of a double ring brick sewer, 41x56 in., and 620 ft. long, also for several small pipe sewers about 3,200 ft. in the aggregate.

Keokuk, Ia.—City Engr. J. Ross Robertson writes that bids are wanted by Rice H. Bell, Clk. of Council, until July 23 for the construction of an 8-in. tile sanitary sewer 1,250 ft. long, 800 cu. yds. of excavation, 75 inlets, 3 inspection pipes and 1 flush tank.

Menasha, Wis.—Bids are wanted July 22 for the construction of sewers in 3 streets. S. S. Little, City Clk.

Danville, Ill.—City Engr. W. H. Martin writes that J. H. Palmer has received the contract for constructing 600 ft. of 36-in., 1,400 ft. of 30-in. and 300 ft. of 18-in. pipe sewer for $5,690.

San Antonio, Tex.—The City Council has ordered a special election July 31 to vote on the issue of $300,000 bonds for improvements, including sewerage, asphalt paving and iron bridges.

Portsmouth, O.—Bids are wanted Aug. 5 for improving, by grading and constructing necessary sewers, culverts and drains, several streets. R. C. Bratt, City Engr.

Cleveland, O.—The lowest bid opened July 10 for constructing a main intercepting sewer in a portion of Lake St. was from W. J. Gawne, of Cleveland, at $191,100.

Lewiston, Idaho.—City Engr. Ernest McCullough writes that the sewer project has been abandoned for the present.

Birmingham, Ala.—Local press reports state that the Jefferson County Sanitary Comn. has accepted the joint proposition of the Donelson Const. Co., C. M. Burkhalter & Co., and the Pennington Const. Co., for constructing the main county sewer. The cost of same will be about $300,000. According to plan C, which was adopted, the prices to be paid for the work are as follows: 4-ft. sewer, $2.52½ per ft.; 4-ft. 6-in. sewer, $2.82½ per ft.; 5-ft. sewer, $3.14½ per ft.

Newport, Ky.—The Bd. of Sinking Fund Comrs. has sold sewer bonds to the amount of $43,000.

Montreal, Que.—Local press reports state that the contract for continuing the St. James St. auxiliary sewer westward has been awarded to M. Dineen at $27.98 per lin. yd., and if there is any rock excavation to be done a charge of $3.50 per cu. yd. extra.

Sharon, Pa.—Local press reports state that the Council is about to issue $40,000 bonds for the completion of the sewer system.

Hudson, N. Y.—Supt. of Pub. Wks. H. K. Bishop writes that the contract for 1,125 ft. of 4-ft. brick sewer, with appurtenances, has been awarded to Smith Patterson, of Hudson, N. Y., for $7,950.

Hampton, Ia.—Consulting Engr. M. Tschirgi, Jr., of Dubuque, writes that the contract for constructing 23,250 ft. of 8 to 15-in. pipe sewers, with 46 manholes and 10 flush tanks, has been awarded to O. G. Kringle, of Dubuque, at 60 cts., 75 cts. and 50 cts., respectively, for 15, 12 and 8-in. vitrified pipe, $60 for flush tanks, $30 for manholes, $5 for syphons, and $4 for rock excavation; total, $14,166. Average depth of excavation to be 9 ft., principally in loam and clay, with 600 cu. yds. stone.

St. Joseph, Mo.—Mayor Borden has signed the ordinance providing for the completion of the Main St. sewer, which is to be 2.3 ft.x3 ft. in diameter, 1½ rings of hard-burned brick, laid in hydraulic cement mortar. Appropriation, $8,000.

Cincinnati, O.—Bids will be received by the Bd. Pub. Service, July 23, for constructing sewers and drains in Findlay St.; also on Aug. 13 for constructing a trunk sewer and drains on Jerome Ave. Geo. F. Holmes, Clk.

Norristown, Pa.—Bids are wanted Aug. 13 for the construction of salt-glazed vitrified pipe sewers, with laterals to the house line, and appurtenances, on numerous proposed sewers. John H. Rex, Chmn. Sewer Com.

Watertown, N. Y.—Bids are wanted by the Bd. Pub. Wks., July 21, for the construction of sewers in 3 streets. C. O. McComb, City Engr.

Muncie, Ind.—Bids are wanted July 28 for the construction of Plum St. sewer No. 1, to be of vitrified pipe, 8 inches in diameter. F. W. Clevenger, City Clk.

Cleveland, O.—Bids are wanted July 29 for the construction of sewers in 6 streets. Chas. P. Salen, Dir. Pub. Wks.

Watervliet, N. Y.—Bids are wanted July 23 for the construction of a 15-in. and an 18-in. sewer. Luhr Eggers, City Clk.

Zanesville, O.—Bids are wanted July 26 for furnishing material and labor for the construction of a sewer on Harrison St. C. W. McShane, City Clk.

Darlington, S. C.—A commission for a charter has been issued to the Darlington Sewer Co., which proposes to build and equip a sewerage system for the city of Darlington. Incorporators: W. F. Dargan, N. L. Harrell, W. L. Galloway, R. L. Edwards.

New Brighton, Pa.—Bids are wanted July 21 for the construction of 8 and 18-in. pipe sewers. F. C. O'Rourke, Boro. Secy.

Saratoga Springs, N. Y.—Bids are wanted July 22 for furnishing labor and material and constructing an 8-in. terra cotta sewer through Warren St. H. F. Thomas, Clk. Sewer, Water & St. Comn.

Verona, Pa.—Sewer bonds to the amount of $33,000 have been sold by the Council.

Ft. Worth, Tex.—The contract for constructing a sewer through the Armour and Swift properties to Marine Creek has been awarded to C. W. Olcott, of Dallas. The sewer will be of 24-in. tile and 30-in. pipe of double strength and 2,500 ft. long, with 22 manholes. Contract price, $23,000.

San Francisco, Cal.—It has been recommended to the Supervisors by the Bd. of of Pub. Wks. that early action be taken to submit a proposal to vote bonds for a new sewerage and drainage system to cost about $6,000,000. In the tax levy just fixed by the Supervisors an allowance of $50,000 was made for the construction of new sewers during the fiscal year.

St. Louis, Mo.—The House of Delegates has passed ordinances for the construction of drainage sewers in the Tower Grove and Rock Districts. Total appropriation, $55,000.

The Bd. of Pub. Improv. has appropriated $11,000 for drainage work on Vandeventer and Washington Aves.

New York, N. Y.—The Bd. of Aldermen has authorized an issue of $100,000 bonds for the repair and reconstruction of sewers in the Boro. of Manhattan.

Pittsfield, Mass.—The Aldermen have adopted an order appropriating $8,500 for surface drainage.

Minneapolis, Minn.—The City Council Com. on Sewers and Paving has decided that of the $150,000 permanent improvement bonds authorized, $88,000 should be used for paving, $52,000 for sewers and $10,000 for curbing and gutters.

Belleville, Ill.—City Engr. Graver estimates the cost of W. Main St. sewer at about $14,614.

Long Beach, Cal.—The City Trustees have been petitioned to establish a sewer system.

Durand, Mich.—Bids will be received July 28 by Wm. H. Putnam, Village Clk., for 300 ft. of 18-in., 2,000 ft. 10-in., 3,000 ft. of 12-in. and 1,100 ft. 15-in. vitrified pipe sewers.

Youngstown, O.—See "Paving and Roadmaking."

Seattle, Wash.—An ordinance before the City Council provides for the construction of a sewerage system with a septic tank for sewage purification, for Latima and vicinity.

Lancaster, Wis.—Local press reports state that surveys are being made for a sewer system.

Marshfield, Wis.—The City Council has voted to issue $35,000 bonds for a sewerage system.

Avon, N. J.—See "Water."

Greensboro, N. C.—S. M. Gray, of Providence, R. I., has been engaged by this city to advise in regard to improved sewerage works, to consist of intercepting sewers and sewage disposal works.

Mayfield, Ky.—The Council is reported to have voted $50,000 for a sewerage system.

Rochester, N. Y.—John N. McClintock, of Boston, in a report to the city officials, in regard to sewage disposal, estimates the cost of works, which he favors, as follows: Septic tank, having capacity of 5,000,000 gal., $50,000; 6 acres contact bacteria beds, $100,000; 6 acres intermittent filters, $100,000; total, cost, including land and engineering, $250,000.

Oakland, Cal.—City Engr. Turner has prepared plans for a sewer for the East Dist.; estimated cost, $10,760.

St. Charles, Mo.—The City Council has instructed the City Engr. to prepare plans and specifications for a sanitary sewer system.

Worcester, Mass.—The City Council on July 14 adopted orders for a loan of $20,000 for sewer construction, and for the construction of 50 additional filter beds, estimated to cost $60,000.

Boston, Mass.—Mayor Collins in a communication to the Com. on Finance recommends that an item of $100,000 be inserted in the loan bill for abating the sewage nuisance in the Back Bay Fens.

Batavia, N. Y.—This city is considering plans for a new and adequate sewerage system.

Mt. Pleasant, Pa.—At a recent special election it was voted to complete the sewer system at a cost of $16,000.

Berkley, Va.—Local press reports state that contracts will soon be let by the Town Council for extending the sewer system in the 3d Ward, at a cost of $25,000.

Bellevue, O.—The Sewer Com. of the Council has recommended the construction of 2 trunk sewers, estimated to cost $25,000.

Hampton, Ia.—Oliver Kringle, of Dubuque, is stated to have received the contract for constructing a sewer system for $14,166.

Massillon, O.—The Sewer Comn. has decided to recommend to the Council the construction of a sanitary sewer for Duncan and Walnut Sts.

Northampton, Mass.—The Sewer Comrs. have voted to petition the city government for $50,000 for sewer construction.

Williamsport, Pa.—The Select Council has passed the bill which provides $81,000 for the construction of Grafius Run sewer.

Pittsburg, Kan.—Bids are wanted Aug. 2 for furnishing material and labor necessary to construct 12,966½ ft. of 18-in. and 3,750½ ft. 15-in. sewers. A. A. Bumgarner, City Clk.

Muskogee, Ind. Ter.—See "Water."

Plainfield, N. J.—Bids are wanted Aug. 4 for doing the work and furnishing certain of the materials for a storm sewer in Arlington Ave; 600 ft. 30-in., 2,320 ft. 24-in. sewers and 560 ft. 12-in. basin and inlet connections will be required. Jas. T. MacMurray, City Clk.

Parkersburg, W. Va.—Bids are wanted July 23 for 2,725 ft. of 15-in. and 2,210 ft. 8-in. sewers. Jesse L. Cramer, City Clk.

Westfield, Mass.—The State Bd. of Health has approved the plans of Town Engr. O. E. Parks for the surface drainage system.

Syracuse, N. Y.—Bids are wanted July 21 for furnishing material and constructing a 15-in. pipe sewer in W. Fayette St. Geo. J. Wetz, City Clk.

Trenton, N. J.—Bids are wanted Aug. 5 for constructing a sewer in 2d St. and a drain in Southard St. C. Edw. Murray, City Clk.

South Brooklyn, O.—It is stated that bids are wanted July 28 for the purchase of $35,000 sewer bonds. W. T. Pupikoffer, Clk.

Chicago, Ill.—It is stated that bids are wanted July 24 for sewers, curbing and asphalt paving in several streets. J. A. May, Secy. Bd. Local Improv.

Waverly, Ia.—Bids are wanted Aug. 5 for the construction of an 8-in. vitrified pipe sewer. F. H. Munger, City Clk.

Steubenville, O.—City Engr. C. E. Flanagan writes that 1,000 ft. of 15-in. sewer is to be constructed.

Albany, N. Y.—Bids are wanted July 21 for the construction of a vitrified pipe sewer in Central Ave., about 2,760 ft. Isadore Wachsman, Clk. Bd. Contract and Supply.

Toledo, O.—Bids will be received on July 28 for furnishing labor and material and constructing cylindrical pipe sewers, and on Aug. 11 for constructing cylindrical brick and pipe sewers. Chas. H. Nauts, City Clk.

BRIDGES.

Terre Haute, Ind.—Bids will be received by M. G. Hamill, 5th and Main Sts., until July 22 for one 70-ft. single span steel bridge (with 14-ft. roadway set on steel legs 14 ft. long), to be constructed across Clear Creek between the townships of Wabash, Ill., and Sugar Creek, Ind.

Milwaukee, Wis.—Bids are wanted Sept. 5 for constructing a highway bridge across North Menomonee Canal at Muskego Ave. Chas. J. Poetsch, Comr. of Pub. Wks.

General plans have been prepared for the 1st Ave. and 6th St. viaduct, length 2,786 ft., including 2 Bascule bridges over N. and S. Menomonee Canals, 40-ft. roadway, asphalt, and 10-ft. cement walks, plate girder. Estimated cost, $550,000.

Lewisburg, Pa.—The Comrs. of Union Co. and the Street Com. of the Boro. of Lewisburg will receive bids on July 21 for the construction of the substructure and superstructure of a steel girder bridge over Limestone Run, in Lewisburg. W. A. Weidensaal, Chmn., St. Com., Lewisburg.

South Bend, Ind.—The South Bend & Southern Mich. Ry. Co. has awarded to the Canton Bridge Co., Canton, O., the contract for a 3d truss of steel to join the highway bridge over St. Joseph River, 300-ft. span, including steel floor system, at $7,797.

San Jose, Cal.—J. G. McMillan, County Surv., San Jose, is preparing plans for a stone bridge to cross Ligas Creek at Old Gilroy; length of span, 32 ft.; roadway, 30 ft. Contracts for construction will soon be let by the Bd. of Superv.

San Antonio, Tex.—See "Sewerage and Sewage Disposal."

Manila, P. I.—A. L. B. Davies, Secy. Municipal Bd., writes that the time for receiving bids, for a rolling lift bridge, has been extended until Aug. 1.

Cleveland, O.—See "Sewerage and Sewage Disposal."

Erie, Kan.—Co. Clk. B. W. Garvin writes that the contract for constructing 3 steel bridges (bids opened July 12) has been awarded to A. M. Blodgett, Kansas City, Mo., for $6,969.

New Castle, Pa.—See "Electric Railways."

Cincinnati, O.—The Bd. of Pub. Service has been requested to take steps leading to the construction of a viaduct from 4th St. at Pike to some point in Mt. Adams. Estimated cost, $1,000,000.

Grand Rapids, Mich.—It is reported that the North Park Bridge Co. has secured the issue of $40,000 bonds for constructing North Park bridge.

Kenosha, Wis.—City Engr. Moth is reported to have begun plans for a steel bridge over the West Middle St. crossing of Pike River.

Lewiston, Idaho.—It is stated that surveys are being completed for the R. R. bridge over the Cumberland River by Engr. Shaw.

Washington, D. C.—Two plans have been proposed for a viaduct over the Mill St. crossing at Summit St., one to cost about $100,000, the other $50,000.

Bloomsburg, Pa.—Local press reports state that J. C. Brown has been selected to prepare plans and specifications for a Co. bridge over the Susquehanna at Mifflinville.

Knoxville, Tenn.—Efforts are being made to secure a viaduct on Church or Clinch Aves. to connect West Knoxville with the old city proper.

Fonda, N. Y.—The Bd. of Supervs. is stated to have authorized the issuance of $30,000 bonds by the towns of Canajoharie and Palatine in payment for the new river bridge.

Oshkosh, Wis.—Plans and specifications have been made for a double track steel bridge to be built across Fox River by the Wisconsin Central R. R. Co., to be used jointly with the Chicago, Milwaukee & St. Paul R. R. R. B. Tweedy, Ch. Engr., Milwaukee.

Pittsburg, Pa.—It is reported that an ordinance granting permission to erect a viaduct from Cable Ave. to Oak Hill, nearly ¼ mile, was given a first reading by the Borough Council of East Pittsburg. The object is to give room for Pennsylvania R. R. yards.

Regency, Tex.—Local press reports state that the Comrs. Court has closed a contract with the Midland Bridge Co., of Kansas City, for a steel bridge over Colorado River, for $8,300.

Cherry Valley, Ill.—It is reported that Darse & Hughs secured the contract for a bridge over the south branch of Kishwaukee River for $8,490.

Altoona, Pa.—It is reported that the 17th St. bridge is likely to be rebuilt this summer.

Anderson, Ind.—It is reported that the city will probably order an iron bridge across Greens Branch at 22d St. to replace one that collapsed.

Harrisburg, Pa.—According to press reports the State will spend within the coming year from $400,000 to $500,000 for 21 bridges destroyed by floods and fires in the following counties; Juniata, Clearfield, Berks, Carbon, Forest, Bradford, Jefferson, Lycoming, Lackawana, Wyoming, Sullivan, Wayne and Luzerne. The following engineers are among those preparing plans: M. D. Bowman, Mahanoy City; O. E. Thompson, Phoenixville; Emil Swensson, Frick Bldg., Pittsburg.

The Harrisburg Bridge Co., it is reported, will increase its capital by an issue of $85,000 in stock and the same amount in bonds, for the purpose of building a bridge over the Susquehanna.

Macon, Mo.—It is reported that the A. M. Blodgett Bridge Co., of Kansas City, has been awarded the contract for 20 steel bridges in Macon Co.

Waterloo, Ia.—It is stated that the Bd. of Superv. has awarded the contract for the steel bridge across Big Creek at La Porte City to the Kansas City Bridge Co. for about $10,000.

Rockwood, Tenn.—It is reported that the contract for the steel superstructure of the Tennessee Central bridge over the Cumberland, near Hyde's Ferry, has been awarded to the American Bridge Co. for $70,000. Total cost of bridge, $150,000.

Beaver, Pa.—Press reports state that a bridge is to be built over the Ohio from about 300 ft. south of the south line of Monaca borough to the end of 3d St. in the borough of Freedom. Among the incorporators are J. T. Reeves, F. F. Brierly and F. G. Barker.

Grand Forks, Minn.—Press reports state that an iron bridge is contemplated over Red Lake River to connect with East Grand Forks.

Springfield, Mass.—Press reports state that a special Comn. to have control of widening the St. James Ave. bridge over the N. Y., N. H. & H. R. R. tracks has been appointed. The members are L. A. Frothingham and M. J. Murray, of Boston, and Clinton White, of the State R. R. Comn.

Las Animas, Colo.—It is reported that the Bullen Bridge Co. has secured contracts for Co. bridges to the amount of $11,460.

Pueblo, Colo.—Local press reports state that City Engr. Wm. Peach will at once prepare plans for improving the Northern Ave. viaduct. Appropriation, $9,000.

Arkwright, N. Y.—Press reports state that the Rochester Iron Bridge Construction Co. has secured the contract for 12 iron bridges at a total of $15,000.

Chambersburg, Pa.—Local press reports state that the Cumberland Valley R. R. intends to construct a stone arch at Falling Waters, W. Va., to replace trestle. M. C. Kennedy, Vice-Pres.

Wheeling, W. Va.—The Baltimore & Ohio bridge over Wheeling Creek on the Pittsburg Div. is reported washed away. J. E. Grenier, Bridge Engr., Baltimore, Md.

South Bristol, N. Y.—Press reports state that Superv. F. B. Holcomb is making arrangements to raise $20,000 bonds to pay for repairs to highways and bridges.

Glenwood, Pa.—Press reports state that the Baltimore & Ohio R. R. intend to reconstruct the bridge over the Monongahela at a cost of $200,000, contracts to be let in the near future. J. E. Greiner, Bridge Engr., Baltimore, Md.

Des Moines, Ia.—Local press reports state that the Chicago Great Western R. R. bridge has been washed out. Loss, $20,000.

St. Paul, Minn.—It is reported that $28,000 of the annual appropriation will be used for road and bridge improvement during the coming year.

Berkley, Pa.—Press reports state that an iron bridge is wanted to replace stone arch crossing the Davis Mill dam.

Ellijay, Ga.—It is stated that bids are wanted July 25 for building a bridge over the Cartecay. Bridge to consist of 3 spans, a center-span, high-truss pattern, 60 ft. in length and end spans respectively 25 and 36 ft. long. J. C. Allen, Co. Ordinary.

Pembroke, Ont.—It is stated that bids are wanted Aug. 2 for constructing a stone or steel bridge with stone abutments over Bonnechere River, at the village of Eganville. S. E. Mitchell, Co. Clk., Pembroke.

St. Louis, Mo.—See "Railroads."

Carrollton, Mo.—Bids are wanted Aug. 5 for the construction of several wood or steel bridges. Silas Ballard, Bridge Comr.

Painesville, O.—It is reported that the Lake Co. Bd. has passed a resolution in favor of a bridge over Chagrin River, north of Willoughby village; cost to be between $10,000 and $30,000.

Struthers, O.—Press reports state that the Pittsburg & Lake Erie R. R. will probably erect an overhead bridge near the Youngstown Iron, Sheet & Tube Co.'s mill. J. A. Atwood, Ch. Engr., Pittsburg, Pa.

Galena, Ill.—The Comr. of Elizabeth Township is reported to have petitioned for aid in building a bridge over Apple River. M. McGuire, Co. Clerk.

Pittsburg, Pa.—See "Railroads."

Waynesburg, Pa.—Press reports state that Allison's bridge over Ten Mile Creek has been entirely swept away. The approaches to the Buchanan bridge are also reported washed away, together with the Co. bridge just below.

Oneonta, N. Y.—The Structural Iron & Steel Co., of Baltimore, Md., is reported to have secured the contract for the steel bridge over the D. & H. track on Main St., for $29,365.

Cross Keys, Pa.—Press reports state that plans for the Berks Co. bridge over the Schuylkill here, to be rebuilt by the State, are being prepared by M. D. Bowman, of Mahanoy City, and contract will be let as soon as they are ready.

Gallipolis, O.—Local press reports state that the contract for the 100-ft. bridge over the Chickamaugua has been let to the Columbia Bridge Co.

Nebraska City, Neb.—Press reports state that the Co. Comrs. estimate the Co. bridge loss, due to floods, at $50,000.

McMinnville, Tenn.—The Nashville Bridge & Construction Co. is reported to have been awarded the contract for 4 Co. bridges for $9,000.

The Co. Court is reported to have authorized the rebuilding of 2 bridges at Hennessee's Ford and Falls City.

PAVING AND ROADMAKING.

Atchison, Kan.—The City Council has passed a resolution declaring it necessary to pave 10th St. with vitrified brick. Fred Giddings, City Engr.

Tacoma, Wash.—The Council has voted to pave St. Helen's Ave. with bituminous macadam.

Mobile, Ala.—City Engr. D. M. N. Ross writes that the City Council and the Bd. of Pub. Wks. have agreed on the extension of the paving district; the next specification will call for 30,000 yds. of rock asphalt and 16,000 yds. brick laid on a sand foundation. Contracts for this work will soon be let. J. N. Hazelhurst, Engr. Bd. of Pub. Wks., in Charge.

San Antonio, Tex.—See "Sewerage and Sewage Disposal."

Rock Island, Ill.—City Engr. Wallace Treichler writes that the City Council has passed an ordinance for the paving of 2 blocks on 21st St. with asphalt. Estimated cost, $8,700.

Freehold, N. J.—The Bd. of Chosen Freeholders is stated to have awarded contracts for constructing county roads as follows: Macadam road between Keyport and Keansburg, to Fields & Swackhammer, at 71 cts. per sq. yd., total $10,575; stone road, from Matawan Station to Freneau, to J. R. Shanley, at 66 cts. per sq. yd., total $9,270; stone road, with gravel surface, between Monmouth Beach and North Long Branch, to J. R. Shanley, at 91 cts. per sq. yd., total $15,083.

Des Moines, Ia.—The City Council on July 7 ordered portions of E. 12th, E. 2d and E. 1st Sts., Mary Ave. and 2 alleys paved with brick; also curbing for 11th, 1st, 2d and Des Moines Sts.

Atlantic City, N. J.—State Road Comr. Henry I. Budd, Trenton, has recommended the construction of a new stone road between Atlantic City and Pleasantville; also that the State pay 1/3 of the cost, which would probably be about $150,000.

Huntington, L. I., N. Y.—Edwin Bailey, Jr., of Patchogue, is Chmn. of the Com. appointed by the Suffolk County Bd. of Supervisors to investigate the question of cross island roads to be built under State aid, as provided by the Higbie-Armstrong law.

Worcester, Mass.—Mayor Edw. F. Fletcher has directed Street Comr. Wright S. Prior to take immediate action toward repaving Main St. with granite block on a Portland cement concrete base.

Jersey City, N. J.—Local press reports state that the old Belleville turnpike, also known as Arlington turnpike, extending from Newark turnpike to Belleville bridge, is to be widened to 100 ft. and macadamized under the State road act, according to a resolution recently adopted by the Hudson Co. Bd. of Freeholders.

Watertown, N. Y.—The only bid received for sheet asphalt paving on a portion of Washington St. is reported to have been from the Barber Asphalt Paving Co. at $1.98 per sq. yd.; total, $25,188.

Cincinnati O.—The Bd. of Pub. Service has decided to pave several streets on Mt. Adams with brick and asphalt.

Fulton, N. Y.—The Bd. of Pub. Wks. has decided to pave portions of Oneida St. with brick, First St. with asphaltum and Broadway with either brick or asphaltum.

Alexandria, Ind.—The Council is stated to have awarded contracts for improving Madison and Liberty Sts. to F. M. Kemp & Sons, of Middletown, O., at $18,277, or $8.27 per ft. for Madison St., and $4,722, or $7.75¼ per ft. for Liberty St.

Rome, N. Y.—The Common Council has adopted plans and specifications for the paving of a portion of West Embargo St. with either asphalt, macadam or brick.

St. Paul, Minn.—The estimated cost of paving Ramsey St. from W. 7th St. to Pleasant Ave. with asphalt is $13,104 for the city's part and $9,140 for the street railway's portion, or at the rate of $5.31 a front ft. It is estimated that the city's part would cost $11,265, or $4.56 a ft., if paved with brick, and with sandstone, $14,203, or $5.78 a ft.

Mayor Smith has vetoed the Council's final order for paving with sandstone, W. 7th St. from Ramsey to Tuscarora Sts. The majority of the property owners are said to favor asphalt paving for this street.

City Engr. Rundlett estimates the cost of paving University Ave. at $84,118 for asphalt, and $93,349 for sandstone.

The Bd. of Pub. Wks. has decided to pave Robert St. with brick. Estimated cost, $22,792.

North Adams, Mass.—Bids will be received by Comr. Temple, July 23, for paving Holden St. with vitrified brick; 2,300 sq. yds.

Haddonfield, N. J.—The Bd. of Co. Freeholders, Camden, has instructed the Co. Engr. to prepare plans and specifications for the stoning of Haddonfield and Gibbsboro road.

Norristown, Pa.—The Schuylkill Valley Traction Co. (G. Hoeger, Supt., Norristown), will pave with Warren's bituminous macadam waterproof pavement on De Kalb St. for a distance of 3,410 ft.x36 ft., for the privilege of extending its tracks to the Boro. line.

Port Huron, Mich.—The Common Council on July 7 rejected all bids for paving 7th St. and instructed the Supt. of Pub. Wks. to ask for new bids on Warren's bituminous macadam, brick, tar macadam or asphalt block.

Elizabeth, N. J.—Bids are wanted Aug. 1 for 6,480 sq. yds. of oblong trap block pavement in Livingston St., with 3,100 ft. of curb reset and 100 ft. of new curb. W. H. Luster, Jr., City Surveyor.

Auburn, N. Y.—City Clk. E. H. Herrling writes that bids will probably be received this month for asphalt pavement in one of the principal streets; estimated cost $30,000, and bids will probably be asked in Aug. for asphalt paving in another street; estimated to cost $6,000.

Harrisburg, Pa.—Bids are wanted July 21 for paving Short St. with Warren's bituminous macadam waterproof pavement and curbing with bluestone.

Champaign, Ill.—Bids are wanted July 21 for paving and curbing Park St.; 6,450 sq. yds. of brick will be required. C. J. Mullikin, Chmn. Bd. Local Improv.

Mt. Vernon, O.—The contract for paving Gambier St. with Townsend's wire-cut fireclay block on gravel foundation, with Murphy grout filler and Berea sandstone curb, has been awarded to W. J. Berry. The total cost is said to be about $28,744.

Pittsburg, Pa.—The grand jury has approved the proposed improvement of the following roads: Steubenville pike, Chartiers township; parts of Washington pike, Scott township; Pitcairn road, Patton township; Oakdale and McDonald road, North Fayette township; Middleton and Ewing's mill road, Stowe and Robinson townships.

Windsor, Conn.—Bids will be received by the Bd. of Selectmen, July 23, for the construction of a macadam road. T. S. Loomis, 1st Selectman.

Norwich, N. Y.—Bids are wanted July 28 for paving Lock St., 2,320 sq. yds. vitrified brick, and 1,900 lin. ft. of stone curbing will be required. A. R. Chonles, Clk. Bd. Village Trus.

Crookston, Minn.—City Clk. W. A. Lanctot writes that bids are wanted Aug. 12 for asphalt paving, estimated to cost $40,000. Geo. A. Ralph, Engr. in Charge.

Chattanooga, Tenn.—Local press reports state that the only bid received July 8 for the paving of W. 9th St. was from the Southern Paving & Construction Co. at $2.70 per sq. yd.; the contract calls for 1,728 sq. yds. of asphalt paving, 180 sq. yds. of brick guttering, and 30 sq. yds. of brick crossings.

Boston, Mass.—Jas. Donovan, Supt. of Streets, has placed the estimated cost of paving with granite block and regulating Norfolk Ave. from E. Cottage St. to the New England R. R., at $10,500.

Irvington, N. J.—The Special Speedway Com. of the Bd. of Freeholders has decided to locate the proposed driveway for fast horses in the town of Irvington. There is an appropriation of $22,000 for grading, paving and beautifying this roadway.

Newark, N. J.—The Bd. of Pub. Wks. has awarded the contract for paving Mott St. to the Barber Asphalt Paving Co., for $8,600.

Owosso, Mich.—The Common Council has ordered the Bd. of Pub. Wks. to get estimates for a macadam or crushed stone pavement on W. Main St.

Burlington, Ia.—Bids are wanted July 21 for paving 2 streets with brick. Emmet Steece, City Engr.

Watertown, N. Y.—Bids are wanted July 21 for about 15,500 sq. yds. of bituminous macadam waterproof pavement, with trap rock surface; also for 3,275 sq. yds. brick pavement. C. O. McComb, City Engr. Estimated cost, $45,000.

Toledo, O.—Bids are wanted Aug. 11 for paving Union and Cherry Sts. with block. Chas. H. Nauts, City Clk.

Chicago, Ill.—See "Government Work."

North Bend, O.—Corp. Clk. W. D. McClurkin writes that on July 14 it was voted to issue $20,000 bonds for sidewalks and street improvements.

Redlands, Cal.—Street improvement bonds to the amount of $50,000 have been sold.

Wilkesbarre, Pa.—Local press reports state that the contract for resurfacing certain asphalt streets has been awarded to the Warner-Quinlan Asphalt Co., Syracuse, N. Y., at $1.25 per sq. yd. for 28,000 sq. yds. of asphalt, $6 per cu. yd. for 300 cu. yds. of binder and $4.25 per cu. yd. for 1,000 cu. yds. of binder and $4.25 per cu. yd. for 1,000 cu. yds. of concrete; total, $41,050.

Covington, Ky.—Mayor Johnson has approved the ordinance authorizing the issue of street improvement bonds to the amount of $100,000.

Greenwich, Conn.—Bids will be received July 26 by S. D. Minor, Room 5, Trust Bldg., for macadamizing about 6,000 ft. of road for the Field Point Land Co.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service, July 30, for paving Westside and Eastside Aves. with macadam, and Kuhlman Ave. with brick; also on Aug. 12 for paving Beekman St. with granite block and Jones St. with brick; also on Aug. 13 for paving Southside Ave. with macadam. Geo. F. Holmes, Clk.

Chicago, Ill.—See "Sewerage and Sewage Disposal."

Centerville, Ind.—It is stated that bids are wanted Aug. 24 for 40,000 sq. ft. cement on brick sidewalks. J. F. Frame, Res. Engr.

Lincoln, Neb.—It is stated that bids are wanted Aug. 4 for the purchase of $215,000 paving and other improvement bonds. B. C. Fox, City Treas.

Toronto, Ont.—It is stated that bids are wanted July 22 for asphalt, cedar block, tar-macadam and other paving, and concrete sidewalks in 30 streets. G. H. Howland, Chmn. Bd. Control.

Albany, N. Y.—Bids are wanted July 21 for paving 3 streets with vitrified paving blocks and 1 street with granite block. Isadore Wachsman, Clk. Bd. Contract and Supply.

Oneida, N. Y.—A press report states that bids will be received by the City Clk. Aug. 4 for the purchase of $20,000 bonds, for paving Main St. and Lenox Ave.; also for $5,000 sewer bonds.

Paoli, Ind.—Bids are wanted Aug. 4 for construction of about 35,246 ft. of new road in Orangeville Township, to be of gravel or macadam. Geo. T. Tegarden, Co. Aud.

Topeka, Kan.—The Road & Bridge Com. of the Commercial Club has presented to the Co. Comrs. a petition for a 20-ft. pavement of vit. brick to extend from the end of the W. 6th Ave. pavement to the Kansas River bridge. Probable cost about $12,000.

Verona, Pa.—Paving bonds to the amount of $12,000 have been sold.

Nashville, Tenn.—It is proposed to pave a portion of Broad St. and West End Ave. with bituminous macadam, at a probable cost of $28,000.

Sandusky, O.—According to plans and specifications prepared by City Engr. Miller, the estimated cost of paving a portion of Hayes Ave. with different materials would be as follows: Brick, $28,860; block asphalt, $40,915; sheet asphalt, $36,200; bituminous macadam, $31,368.

New York, N. Y.—The Bd. of Aldermen on July 15 approved an appropriation of $1,250,000 to regulate and grade the Grand Concourse.

Albany, N. Y.—The Mayor has signed ordinances for the paving of portions of Van Zandt, Fulton and Plain Sts.; also the repaving with sheet asphalt of a portion of Broadway.

Chicago, Ill.—The Comrs. of North Shore Park Dist. have instructed the Board's attorney to draft an ordinance for the paving and improvement of Pratt boulevard from Clark St. to the lake, at a cost of $31,000.

Winnipeg, Man.—The City Council has given notice of intention to pave a portion of Young St. with asphalt, at an estimated cost of $11,985. C. J. Brown, City Clk.

Bridgeport, Conn.—Bids will be received July 29 by the St. Com. of Common Council for the construction of a macadam and telford road.

Cortland, N. Y.—Local press reports state that Port Watson St. is to be paved with macadam, at an estimated cost of $15,900.

Minneapolis, Minn.—See "Sewerage and Sewage Disposal."

East Hampton, Conn.—The Selectmen were authorized at a recent town meeting to construct a new highway north from Mill St.

Emeryville, Cal.—Local press reports state that the Town Trustees have awarded contracts for street work amounting to $48,500 to Hutchinson, Ransome & Co., of Oakland, their detail bid being as follows: Grading, 1 ct. per sq. ft.; wooden curbing, 10 cts. per lin. ft.; paving and grouting gutter, 9½ cts. per sq. ft.; bituminous crosswalks, 17 cts. per sq. ft.; 7x30-in. square cast iron culverts, $3.50 per lin. ft.; and macadamizing, 10 cts. per lin. ft.

Youngstown, O.—It is reported that bids are wanted Aug. 2 for paving Holmes St.; also for the construction of a sewer in Wilson Ave. C. E. Cross, Clk. City Comrs.

Grossepointe, Mich.—The Township Bd. is stated to have awarded the contract for macadamizing Jefferson Ave. to Jas. Hanley for $92,274.

Denver, Colo.—The following bids were opened July 9 for grading and curbing Capitol Hill Improv. Dist. No. 2: R. P. McDonald, $90,740; The Colorado Co., $90,325; J. M. O'Rourke Con. Co., $87,630; Western Realty & Paving Co., $90,398; John Gaffy, $92,790; Thomas J. Tully, $80,519.

Superior, Wis.—The contract for paving the strip between the outside rails of the street car tracks has been awarded by the Council to P. McDonald, of Duluth, for $11,000.

Leavenworth, Kan.—The Council has passed resolutions to pave a portion of 4th St. with brick and a portion of Broadway with asphaltum.

Milwaukee, Wis.—Bids are wanted July 22 for repaving 16th St. viaduct with creosoted pine blocks. Estimated cost, $40,000. Chas. J. Poetsch, Comr. of Pub. Wks.

Chester, W. Va.—A vote will be taken July 28 on the question of issuing $20,000 bonds for street paving.

East Liverpool, O.—Bids are wanted July 28 for paving College St. and Drury Lane with brick.

Menominee, Mich.—The City Council has directed the City Engr. to prepare plans and specifications for a brick pavement on Main St. from Ogden Ave. to the lower bridge.

Detroit, Mich.—Local press reports state that the following are the lowest bids received July 10 for paving portions of numerous streets: Cedar—Adelaide St., J. A. Mercier, $1,893; per sq. yd., $1.62; 24th St., W. E. Lennane, $12,774, or $1.44 per yd.; Vinewood Ave., J. A. Mercier, $8,896, or $1; Lebrosse St., W. E. Lennane, $8,111, or $1.49; Congress St., A. Grant, $8,975, or $1.51; St. Aubin Ave., J. Grant, $8,755, or $1.42; Wabash Ave., J. A. Mercier, $7,298, or $1.52; Humboldt Ave., J. A. Mercier, $8,080, or $1.60; Wabash Ave., J. A. Mercier, $7,273, or $1.51; High St., J. Porath, $6,578, or $1.51; Brick—Forest Ave., J. McLoughlin, $12,818, or $1.93; Hastings St., W. Lappin, $8,333, or $1.98; Beaubien St., J. A. Mercier, $11,746, or $2.02.

Brooklyn, N. Y.—The Interstate Paving Co., of Utica, was lowest bidder for four contracts for asphalt paving, for which bids were opened July 11, the four bids amounting to $30.030. The detailed bids on the largest contract, for Dean St., were as follows: A, Interstate Paving Co.; B, Bklyn. Alcatraz Asph. Co.; C, M. T. Meagher; R. Cranford Co.; E, Green River Asph. Co.; F, Uvalde Asph. Co.:

	Asph., 4,305 sq. yds.	Conc., 598 cu. yds.	Excav., 1,657 cu. yds.	Conc. curb, 2,330 ft.	Cement walk, 11,602 sq. ft.	Total.
A	$1.32	$1.10	$.25	$.50	$.18	$10.008
B	1.40	5.25	.40	.55	.15	12,851
C	1.65	5.50	.60	.65	.20	15,221
D	1.07	4.25	.30	.60	.16	10,899
E	1.25	4.00	.30	.45	.16	11,175
F	1.40	5.00	.30	.45	.15	12,303

Bids were also received for Medina sandstone pavement on concrete foundation, Jas. H. Holmes & Co. lowest bidder in one case, for 1,440 sq. yds. pav't at $2.35 and 280 cu. yds. concrete at $4.75, and T. F. Byrnes in another, for 1,320 sq. yds. pavt. at $2.47 and 270 cu. yds. conc. at $4.60.

M. T. Meagher was lowest bidder for 5,090 sq. yds. granite pavt. on sand for Meserole and Waterbury Sts., including 3,030 ft. bluestone curb and 13,930 sq. ft. cement sidewalks; total of bid, $15,295.50.

POWER PLANTS, GAS AND ELECTRICITY.

Baltimore, Md.—The Continental Trust Co. has financed the scheme for developing the power at three points on the Peach Bottom Rapids of the Susquehanna River. Each station will deliver 50,000 H.-P. The first development calls for two dams of 1,400 and 4,400 ft. and a power station on Lower Bare Island, with ten 5,000-H.-P. units. James H. Harlow, Pittsburg, is engineer of the work, and Dr. Coleman Sellers, John Bogart and Clemens Herschel are among the consulting engineers.

Kirkwood, Ill.—The Village Bd. is stated to have granted a franchise to Clifford West, of Biggsville, Ill., for an electric light plant for Kirkwood.

Lead, S. D.—The City Council is stated to have granted the Dickinson-Ames Co. a franchise for a gas plant.

Kirksville, Mo.—C. H. Payson is stated to have petitioned the City Council for a franchise for a gas plant.

Columbus, O.—Mayor Hinkle is stated to have approved the ordinance granting a franchise to the East Columbus Htg. & Lighting Co.

Redding, Cal.—Bids will be received by the McCloud River Electrical Power Co., Redding, until Aug. 1 for furnishing labor and material to build a dam, canal and power house on McCloud River, about 40 miles n. e. of Redding.

Washington, D. C.—Bids are wanted July 26 for furnishing underground signal and telephone cables for the Fire Alarm and Police Telegraph and Telephone Service in the Dist. of Columbia, during the fiscal year ending June 30, 1903, as advertised in The Engineering Record.

Annapolis, Md.—Baldwin & Pennington, 44 South St., Baltimore, architects, for a central heating and electric light plant, to be constructed at Annapolis, write that as soon as plans and specifications are prepared bids will be asked for said work.

Webster City, Ia.—The City Council is stated to have appropriated $5,000 to construct a municipal heating plant.

Madison, Wis.—The Governor is stated to have approved plans for the new ventilating, heating and electric lighting plant, to be installed in the Capitol, as submitted to him by the Special Commission, consisting of Prof. Storm Bull, Archt., Lew Porter and Prof. Bernard V. Swenson; estimated cost, $60,000.

Boulder, Colo.—The Boulder Electric Light & Power Co. is stated to have voted to issue $160,000 bonds. New engines and dynamos are to be purchased, and later the tracks are to be extended to the sanitarium in the northwestern part of town.

Hyattsville, Md.—The Town Council is stated to have received a proposition from the Washington, Baltimore & Annapolis Electric Ry. Co. (Jas. Christy, Vice-Pres., 405 Bond Bldg., Washington, D. C.), for the installation and maintenance of an electric lighting plant in Hyattsville. This company also proposes erecting a power house in Hyattsville for the purpose of furnishing power to the Berwyn & Laurel Electric Ry. and for its own line to Baltimore via Landover.

Carthage, Mo.—D. C. Brainard, of Carthage, is reported to have petitioned the Council for a franchise for a gas plant.

Summit, N. J.—See "Water."

Silverton, Colo.—Town Clk. R. H. Cooper writes that the contract for installing an electric lighting plant has been awarded to Skinner & Sethman, of Denver, for $19,770 (less building); the contract for the building has not yet been awarded.

Batesburg, S. C.—E. F. Strother, Atty., writes that surveys have been started by the Saluda River Electric & Const. Co. for the building of a dam across Saluda River, power house, etc. A. G. La Motte, of Columbia, S. C., Engr. in Charge.

Bennettsville, S. C.—This city will install a complete steam driven electric light plant. Collier & Brown, Consulting Engrs., of Atlanta, Ga., have charge of the work.

Eminence, Ky.—City Clk. W. J. Tutt writes that J. C. Helburn, J. A. Crabb and G. A. Holland, all of Eminence, bought the city franchises for electric light and electric railway.

Grand Rapids, Minn.—Edw. P. Burch, Consulting Engr., 1210 Guaranty Bldg., Minneapolis, writes that the contract for constructing an electric light plant has been awarded to J. G. Robertson, of St. Paul, at $24,800 for steam and electric machinery and $4,200 for the building.

New York, N. Y.—Bids are wanted July 25 by Thos. Sturgis, Comr. Fire Dept., for furnishing and delivering 60,000 ft. of underground telegraph cable, consisting of 20,000 ft. each 16.20 and 26 conductor cable.

Dunn, N. C.—See "Water."

Ferndale, Minn.—O. Claussen, of St. Paul, is reported to be preparing plans for an electric light plant.

Flushing, L. I.—The Newtown & Flushing Gas Co. is stated to have closed a contract with the United Gas Improvement Co., of Philadelphia, Pa., for the installation of a new generating plant at its works here. The new plant will have a capacity of nearly 1,000,000 cu. ft. per day.

Camden, N. J.—The Bd. of Freeholders is stated to have adopted a resolution authorizing the South Jersey Gas, Electric & Traction Co. to lay its pipes on River Road from Camden to the Burlington Co. line.

Cripple Creek, Colo.—The citizens are stated to have voted on June 30 to grant 2 electric franchises, one to H. P. Kerin and the other to the Peoples Electric Light Co.

Davenport, Wash.—C. O. Green is reported to have petitioned for a franchise for an electric light plant.

Waterbury, Conn.—J. Harry and Thos. F. Fagan are reported interested in the construction of an electric light plant.

Fremont, O.—The Logan Natural Gas Co. is stated to have petitioned the Council for permission to lay its pipes and supply natural gas in Fremont.

Chicago, Ill.—The City Council has granted the Chicago Yaryan Co. a franchise to operate a lighting and heating system in the territory bounded by North Ave., 52d Ave., 12th St. and Austin Ave.

Shenandoah, Ia.—The citizens are stated to have voted to grant Mr. Hayes and associates a franchise for a gas plant.

Emporia, Kan.—It is reported that bids will be received by G. O. Mathewson, City Clk., July 24 for 2 alternating current generators and electrical apparatus, and on July 28 for 2 steam boilers and other apparatus for an electric light plant.

New Matamoras, O.—The Council is stated to have granted J. B. Parker, of New Matamoras; C. C. Stover, of Sistersville, W. Va., and others, a franchise to lay a gas pipe system.

Worthington, Minn.—See "Water."

Montreal, Que.—The Standard Light & Power Co. is reported to be considering the construction of a steam heating plant.

Belzoni, Miss.—S. Castleman writes that he will receive bids in about 60 days for the construction of an electric light and power plant.

Constantine, Mich.—It is stated that bids are wanted July 21 for embankment, road work, piling, masonry work, etc., in connection with the proposed power plant for the Constantine Hydraulic Co.

Petersburg, Ind.—Bids will be received by Frank Thomas, Clk. Town Trus., for the construction of an electric light plant.

Lewiston, N. Y.—See "Water."

Helena, Mont.—The new owners of the Helena Power & Light Co. are reported to have incorporated as the Helena Light & Traction Co. The company is empowered to own and improve water power, develop and deal in electricity, gas and steam for all purposes, and to operate street railways to Broadwater, East Helena, Ft. Harrison, Kenwood, Lenox, the University of Montana and other points; capital, $100,000. Directors: Thos. A. Marlow and Norman B. Holter, of Helena, and Kenneth Clark, of St. Paul, Minn.

Hartwell, Ga.—See "Water."

Koala Zumpur, Malay Peninsula.—Bids will be received at the Office of the Crown Agents for the Colonies, Downing St., London, S. W., England, on or before Aug. 21 for the following plant and material in connection with the electricity supply scheme for the town of Koala Zumpur, in the protected Native State of Selangor, Federated Malay States: Contract A—Supply, delivery and erection of generating station, consisting of 2 600 H.-P. high pressure turbines, with pipes; 2 400 Kw. 3-phase alternators; switchboards, etc.; also sub-station plant, consisting of 3 150-Kw. motor generators, 2 balancers, switchboards, etc. Contract B—To supply and deliver, f. o. b., at a European port, steel poles, cross-arms, insulators, copper wire, etc., for high-pressure transmission line. Contract C—To supply and deliver, f. o. b., at European port, arc lamps, iron posts, controlling apparatus, glow lamps and fittings. Specifications, drawings, general conditions and forms of tender may be obtained from the Crown Agent for the Colonies, London, on the payment of £2 for Contract A, £1 for Contract B and £1 for Contract C.

ELECTRIC RAILWAYS.

Cardington, O.—The City Council is stated to have granted a franchise to the Mansfield, Mt. Gilead & Delaware Electric Ry. Co.

Fairfield, Cal.—The Bd. of Superv. is stated to have granted J. E. Woolley, of Vacaville, a franchise for the construction and operation of an electric railway on the public roads of Solano County, to connect Suisun, Vacaville, Winters, Elmira and Cement City.

Norristown, Pa.—See "Paving and Roadmaking."

Tuscumbia, Ala.—J. T. Crass, of Chattanooga, Tenn., is stated to have secured an electric railway franchise.

Oneida, N. Y.—A certificate for the extension of the Oneida Ry., from Oneida to Sylvan Beach, is stated to have been filed with the Secy. of State.

Pontiac, Mich.—The Town Bd. of the Township of Pontiac is stated to have granted a franchise to the promoters of an electric railway which is projected from Pontiac to Flint by way of Drayton Plains, Waterford, Clarkston, Davisburg, Holly and Fenton. Jas. A. Randall, of Detroit, Mich., is reported interested.

Loudonville, O.—The City Council is stated to have granted a franchise to the Wooster & Mansfield Electric Ry. Co.

Kansas City, Kan.—The Kansas City & Olathe Ry. Co. is stated to have petitioned the Wyandotte Co. Comrs. for a franchise to construct a railway from Rosedale to Olathe.

Mt. Holly, N. J.—The Peoples Traction Co. has been incorporated, with a capital of $175,000, to construct an electric railway between Mt. Holly and Burlington. Josiah K. Bougher, of Philadelphia, and Dr. W. C. Parry, of Hainesport, N. J., are among the incorporators.

Rogersville, Tenn.—The Comrs. of Hawkins County are stated to have voted to issue $100,000 bonds to aid W. T. Goffe in the construction of an electric line from Bean Station or Tate Springs, to Gate City, Va.

Sheboygan, Wis.—The City Council is stated to have granted a franchise to the Sheboygan & Elkhart Lake Electric Ry. Co.

Struthers, O.—The Mahoning Valley Southeastern Ry. Co. is stated to have petitioned the Mahoning Co. Comrs. for a franchise in Struthers.

Hamilton, O.—The Butler Co. Comrs. are stated to have granted a franchise to the Hamilton, Eaton & Richland Electric Ry. Co.

Southwick, Mass.—Charles H. Parsons and Fred T. Ley, of Springfield, and A. J. Forward, of Southwick, representing the Southwick St. Ry., have petitioned the Selectmen for franchises to the Westfield and Agawam town lines.

Boulder, Colo.—See "Power Plants, Gas and Electricity."

Wheeling, W. Va.—The Co. Comrs. are stated to have granted the City Ry. Co. a right of way over the Wheeling and Fairmont pike and up the Frazier's run road, to the line dividing Ohio and Marshall Counties.

Coatesville, Pa.—The Council is stated to have granted the West Chester St. Ry. Co. a franchise from the eastern to the western borough lines.

Walla Walla, Wash.—The City Council is stated to have granted F. B. Romo and N. Meliman a franchise to operate a general electric business and lay rails for the construction of a street railway along the streets of the city. It is stated that they propose constructing an electric railway between Dayton, Wash., and Pendleton, Ore., passing through this city. About $1,250,000 will be expended on the project.

Urbana, O.—The Co. Comrs. are stated to have granted a franchise to the Springfield, Piqua & Sidney Traction Co.

Jacksonville, Fla.—The City Council has granted G. W. Shook a franchise to construct and operate a street railway.

Mineola, L. I., N. Y.—The Mineola, Hempstead & Freeport Traction Co. is stated to have petitioned the Bd. of Superv. for permission to build and operate its lines on the Jericho Turnpike and on the Co. highways from Freeport west to the Co. line, and also a spur line from Rockville Center to Long Beach.

Columbus, Ind.—The Co. Comrs. are stated to have granted a franchise to Jos. L. and W. G. Irwin to extend their electric line from Franklin through Bartholomew Co. to this city.

New Castle, Pa.—A charter has been granted to the West Pittsburg Connecting R. R. Co. The new electric railway will be built this summer from Chewton to New Castle, a distance of 9 miles. A bridge with a span of 900 ft. will be built over Beaver River to West Pittsburg. Directors: Henry O. Evans, Chas. A. Glaser, Angus McD. Taylor and others, all of Pittsburg.

Durand, Mich.—D. M. Estey, of Owosso, is reported to have petitioned the Council for a franchsie for an electric railway to be constructed from Durand to Owosso.

Jamestown, N. Y.—The Warren & Jamestown Electric R. R. Co., of Jamestown, has been incorporated to operate an electric railway 10 miles in length; capital, $100,000. Directors: D. H. Siggins, J. M. Siegfried and H. M. Preston, Warren, Pa.

Akron, O.—The Cleveland, Richland & Akron Transit Co. is stated to have purchased a site in this city for a power house.

Elizabeth, N. J.—The East Jersey Traction Co. is reported to be considering the extension of its line from Elizabeth to Rahway.

Helena, Mont.—See "Power Plants, Gas and Electricity."

Knoxville, Tenn.—E. N. Harris, Ch. Engr., has about completed survey for the Knoxville, Kimberlin Heights & Sevierville Electric R. R., from Knoxville to Sevierville, Tenn.

Eminence, Ky.—See "Power Plants, Gas and Electricity."

Harrisburg, Pa.—Bids are wanted July 21 for grading the route of the Singlestown & Blue Mountain St. Ry. Co. G. W. McIlhenny, Secy.

Youngstown, O.—The Youngstown & Southeastern Electric Ry. Co. has been incorporated to construct an electric railway from Youngstown to Struthers and Poland. Incorporators: E. H. Moore, J. Gordon Cook, and others.

Tuscarora, N. Y.—The Tuscarora Valley R. R. Co. has filed with the State R. R. Comrs. a notice of its intention to construct an electric railway in Addison, Tuscarora, Woodhull and Jasper.

Hyattsville, Md.—See "Power Plants, Gas and Electricity."

Sault Ste. Marie, Mich.—Bids are wanted July 24 for the grading, track laying, bridge work, etc., as required on about 8 miles of electric railway construction in this city, for the Trans-St. Mary's Traction Co. Address G. W. Chance, 44 McTavish Bldg.

Canal Dover, O.—Bids are wanted July 24 by the Canton, New Phila. & Coshocton Ry. Co., at Canal Dover, for grading, trestling, pile driving and masonry for 21 miles of road. W. W. Ely, Ch. Engr.

Jasper, Ind.—The Jasper, French Lick, West Baden & Northwestern Traction Co. is reported incorporated, with a capital of $100,000. Incorporators: Sam'l Reavis, J. W. Brown and others, all of Princeton.

RAILROADS.

Orange, Tex.—The Orange & Northwestern R. R. Co. is stated to have filed an amendment to its charter providing for the construction of 350 miles of additional road. The extensions are to be made from a point on the line in Jasper County to Marshall, Tex., a distance of 150 miles, from Buna, Tex., to Corsicana, a distance of 195 miles, and from Orange to West Orange, a distance of 5 miles. J. W. Maxey, Ch. Engr., Orange.

Pittsburg, Pa.—Local press reports state that the Pennsylvania R. R. Co. will expend about $6,000,000 in terminals for Pittsburg. The work is reported to include a bridge from the West Penn. division at the west end over to Herrs Island; also a double track steel bridge over Allegheny River, which, with approaches, will be 2,000 ft. long. W. H. Brown, Ch. Engr., Philadelphia.

Bloomington, Ind.—A press report states that 4 of the townships of Green County have voted a subsidy of about $100,000 for the proposed Indianapolis Southern R. R.

Hannibal, Mo.—The Hannibal Connecting R. R. Co., of Hannibal, has been incorporated, with a capital of $80,000, by J. R. Maxwell, A. Denorve, Henry Groves and others, to construct and operate a road from Itasca to Hannibal, a distance of 8 miles, to connect with the Hannibal & St. Joseph R. R.

Harrisburg, Ill.—A charter is stated to have been granted to the Ohio River Coal & Ry. Co., with a capital of $100,000, to construct a line from a point on the Ohio River near RosecIaire, through Hardin, Pope, Saline and Williamson Counties, to Marion, Ill., and from Harrisburg to Galatia. Incorporators: Collins B. Hubbard, New York City; John W. Shaw, Harrisburg, Ill., and others. Principal office to be at Harrisburg.

Clarinda, Ia.—The Clarinda, College Springs & Southern Ry. Co. has been incorporated, with a capital of $100,000, to build a steam or electric line from Blanchard to Des Moines. Incorporators: E. B. Dunham, A. P. Tukey and others.

Hutchinson, Kan.—The Hutchinson & Arkansas City R. R. Co. has been incorporated, with a capital of $50,000, to construct a railroad from Hutchinson to Keechi. Frank Vincent and W. Y. Morgan, of Hutchinson, are among the directors.

Cleveland, O.—See "Sewerage and Sewage Disposal."

Novinger, Mo.—Bids are wanted by Wm. Kenefick, Centerville, Ia., for about 50 miles of work on the Iowa & St. Louis Ry. from Novinger to Macon City, Mo.

Nashville, Tenn.—It is stated that the Nashville, Chattanooga & St. Louis R. R. Co. is to extend its line from Lebanon to Smithville and from Murfreesboro to Woodbury. Hunter McDonald, Ch. Engr.

El Paso, Tex.—The El Paso & Southern Ry. Co., of El Paso, has been incorporated, with a capital of $2,000,000, to build a belt line around the city of El Paso and touching the territory of Mexico. Distance, about 6 miles. Incorporators: W. G. Choate, A. Courchesue and others, of El Paso.

St. Louis, Mo.—Local press reports state that the St. Louis Terminal Depot Co. has been incorporated, and has for its object the building of a bridge over the Mississippi River at Mullanply St., extensive terminals on the river front, an elevated road to Forest Park and a new depot near 12th St. and Lucas Ave. Incorporators: J. C. Van Blarcom, Vice-Pres. Nat. Bank of Commerce; Edw. G. Goltra, Pres. Amer. Steel Fdy. Co.; Mayor M. M. Stephens, of East St. Louis, Ill., and others.

Acme, Tex.—The Acme, Red River & Northern Ry. Co. has been chartered to construct a railway from Acme, a station on the Ft. Prices bid are per cubic yard. *Accepted bids.

Norfolk, Va.—Local press reports state that Col. P. C. Hains, Lieut. Col. Chas. J. Allen and Maj. J. B. Quinn, Corps of Engrs., U. S. A, have been appointed by Gen. Gillespie, Ch. of Engrs., to superintend the improvement of the waterway in Norfolk harbor.

Bremerton, Wash.—The following bids were opened July 12 at the Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing a coal storage and handling plant at the Navy Yard, Bremerton: *a*, for complete plant, cost not to exceed appropriation, $128,000; *b*, bid made contingent upon additional appropriation of $137,000 being made by Congress: J. J. Meany, Seattle, *a* $260,000, *b* $260,000; Cotton Bros., Oakland, *a* $128,000, *b* $265,000; Puget's Sound Bridge & Dredging Co., Seattle, *a* $128,000, *b* $265,000; Snare & Triest, New York, *a* $265,000, *b* $265,000; W. R. Nichols, Tacoma, *a* $264,800, *b* $264,900.

Cleveland, O.—Bids are wanted at the U. S. Engr. Office until Aug. 14 for improving Sandusky Harbor, O., by dredging, as advertised in The Engineering Record.

Chicago, Ill.—Bids will be received by Col. E. B. Atwood, Ch. Q. M., at the office of the Q. M., Chicago, until Aug. 12, for constructing a macadam road on Ft. Sheridan Military Reservation.

Philadelphia, Pa.—Plans for improving the channel of the Delaware River are reported to have been approved by the Engineer Dept. in Washington, and it is stated that bids will soon be asked by Capt. Spencer Crosby for work under the recent act of Congress, whereby $600,000 was placed at the command of the department for immediate use, and the engineers are empowered to enter into contracts for an additional sum amounting to $2,400,000 for the 30-ft. channel.

Memphis, Tenn.—Bids will be received Aug. 6 by Capt. E. E. Winslow, U. S. Engr. Office, 280 2d St., for constructing, repairing and enlarging levees in Lower St. Francis, White River, Upper Yazoo and Reelfoot levee districts, in all about 1,790,000 cu. yds.

Wheeling, W. Va.—The following bids were opened July 14 by Capt. W. E. Craighill, Corps of Engrs., U. S. A., for building 400 ft. of Chanoine dam, for navigable pass of Dam No. 5, Ohio River:

Items and Quantities.	Robt. A. Cummings, Pittsburg.	Aetna Const. Co., Wheeling.	Evansville Cont. Co., Pittsburg.
Timber:			
Hemlock, 172,937 ft. B. M.	$35.00	$45.00	$57.00
Oak, 15,377 ft. B. M.	70.00	70.00	90.00
Piling:			
Sheet, 40,800 lin. ft.	50.00	65.00	70.00
Round, 11,532 lin. ft.	.50	.50	.60
Filling:			
Stone, 1,427 cu. yds.	3.50	4.50	3.80
Common, 12,292 cu. yds.	.50	1.00	.75
Common excav., 12,157 cu. yds.	.50	.50	.55
Iron & steel, 255,314 lbs.	.04	.04½	.05
Wire rope, 6,450 lin. ft.	.07	.15	.25
Wire rope clips, 486 pieces.	.30	.30	.25
Iron pipe, 2-in., 480 lin. ft.	.35	.40	.50
Iron pipe, 3-in., 824 lin. ft.	.60	.60	.75
Iron pipe, 4-in., 412 lin. ft.	.80	1.00	1.00
Concrete, 6,840 cu. yds.	7.50	7.50	7.50
Total	$95,256	$107,069	$109,414

Pittsburg, Pa.—Separate bids will be received at the office of the City Controller, July 31, for the following work in Schenley Park: Construction of retaining wall between Panther Hollow Bridge and Hall of Botany, stone wall near the Conservatory and asphalt roadway between Panther Hollow Bridge and conservatories. Regrading and repairing of driveway leading to Greenfield Bridge, including necessary excavation and draining. Construction of retaining wall near Greenfield Bridge. J. O. Brown, City Recorder.

St. Bernard, La.—In his report to the Bd. of Comrs. for Lake Borgne Basin Levee Dist., State Engr. Sidney F. Lewis recommends the construction of a new levee in front of Scarsdale plantation, amounting to about 45,000 cu. yds. of earthwork.

Syracuse, N. Y.—City Engr. Frank C. Schnauber, in his report to the Council upon plans for improving Onondaga Creek, estimates the cost of said improvement, according to plan recommended by him, at $42,000, including $12,000, the cost of a new steel girder bridge at Onondaga St.

Monroe, La.—Bids will be received July 31 by W. T. Barham, Pres. Tensas Basin Levee Bd., Monroe, care Col. L. Potter, U. S. Engr. Office, Memphis, Tenn., for the enlargement of Fulton Lake Levee, Desha County, Arkansas.

Redding, Cal.—See "Power Plants, Gas and Electricity."

Washington, D. C.—Bids are wanted Sept. 6 for furnishing and erecting a coal and ash conveying equipment for the Trumbull St. pumping station, as advertised in The Engineering Record.

Sunbury, Pa.—I. H. Dissinger, Clk. of Council, writes that bids will be received July 25 for river bank improvement, estimated to cost $30,000. Geo. F. Keefer, Engr. in Charge.

St. Louis, Mo.—Bids will be received by Isaac S. Taylor, Dir. Wks., Administration Bldg., World's Fair Site, until July 22 for the construction of a wooden conduit under waterways.

NEW INDUSTRIAL PLANTS.

A. D. Beatson, Tryon, N. C., is interested in the erection of a 2-story, 100x40-ft. knitting mill.

The Buffalo Cotton Mills, Union, S. C., are in the market for a 20-ton ice plant and a 20-ton cottonseed-oil mill. L. G. Young, Engr.

The Portsmouth, O., Cereal Co. has been organized, with a capital of $30,000, and will erect a 150x100-ft. mill with an elevator in connection with it. The plant will use about 3,000 bu. of corn daily.

The Ozark Cold Storage Co., Mountain Grove, Mo., is in the market for machinery for a 2-story, 100x137-ft. building for storing 20,000 bbls. of apples.

The Donovan Wire & Iron Works, Toledo, O., have bought a tract of land, on which they propose to erect new factory buildings.

The Truesdell Elevator Co., Minneapolis, Minn., has been incorporated, with a capital of $100,000, and will build elevators in Western Canada. Probably 12 of them will be built this year.

The Samson Iron Works, Stockton, Cal., will erect a $50,000 plant within a few months. The power plant will consist of several oil engines made by the company.

The Signa Chemical Co., Wiscoy, N. Y., will erect a 44x100-ft. factory building. An office building and power house, for which plans have not yet been drawn, will also be erected. About 1,300 H.-P. electric power will be developed.

Steinberger & Marriott, Rockwell City, Iowa, are erecting a brick plant to have a daily capacity of 30,000 brick.

The Westbrook, Minn., Milling Co. is erecting a 3-story and basement, 30x58-ft. mill, 16x30-ft. engine room, 18x30-ft. boiler room and a coal room 18-ft. square. A Corliss engine will be installed.

The Brookside Mills, Knoxville, Tenn., are ready to begin the extension of their plant to three times its present capacity. About 800 people are now employed. The company will also build 100 cottages. W. T. Lang, Supt.

PROPOSALS.

Proposals for Furnishing Sand.

Office of the Board of Public Works.
POUGHKEEPSIE, N. Y., July 15, 1902.

Sealed proposals will be received at this office until 8 o'clock P. M., Tuesday, July 29, 1902, for furnishing about 2,000 cubic yards of sand for filter beds. Specifications can be obtained on application to the undersigned. The right is reserved to reject any or all proposals.

CHAS. E. FOWLER,
Superintendent of Public Works.

Sewers.

PITTSBURG, KANSAS.

Sealed bids will be received until 5 o'clock P. M., August 2, 1902, by the City Clerk of the City of Pittsburg, Kan., for furnishing all material and performing all labor necessary to construct 12,966½ ft. of 18-in. Sewer and 3,750½ ft. of 15-in. Sewer.

All bids must be made upon the forms prescribed by the City, and be accompanied by a certified check upon a local Bank of the City in the sum of $250, payable to the Treasurer of the City of Pittsburg, to be forfeited in event the bidder fails to enter into contracts with good and sufficient bonds to construct said sewers according to the plans and specifications within ten days of notice of award.

The City reserves the right to reject any and all bids.

A. A. BUMGARNER,
City Clerk.

Water-Works.

MANNINGTON, W. VA.

Bids will be received until 9 o'clock P. M., July 23, 1902, for the following:

1,900 ft., 10-in. cast-iron pipe;
100 " 6-in. " "
1,500 " 8-in. " "
400 " 4-in. " "
4 10-in. cast-iron gates;
4 8-in. cast-iron gates;
6 6-in. stand. fire hydrants, buried 4 ft.;
Roadway boxes for gates, cast-iron;
Fittings and specials for above pipe.

Bids will be for doing the labor alone; and for doing the labor and furnishing the pipe; and furnishing pipe, etc.; alone.

A certified check for 5 per cent. of contract is required to accompany bid.

The Water Committee reserves the right to reject any or all bids.

B. E. MITCHELL,
Chairman Water Committee.

Storm Sewer.

PLAINFIELD, N. J.

Sealed proposals for doing the work and furnishing certain of the materials for the construction of a Storm Sewer in Arlington Ave., will be received by the Common Council of the City of Plainfield, on Monday, Aug. 4, 1902, at 8 P. M., at the Council Chamber.

Each proposal must be accompanied by a certified check for $300, payable to the Treasurer of the City of Plainfield.

The Engineer's approximate estimate of the quantities of materials required, and the work to be done is as follows:

600 ft. 30-in. sewer;
2,320 ft. 24-in. sewer;
560 ft. 12-in. basin and inlet connections;

Above to include trenching, laying and cementing sewer, and backfilling; pipe to be furnished and delivered on the ground by the city:

3 manholes;
18 branches on 24-in. sewer;
4 catchbasins;
20 inlets;
40 cu. yds. concrete.

Copies of plans, forms of proposal, specifications, contract and bond, may be examined at the office of the Engineer, 149 North Ave., Plainfield, N. J.

The right to reject any or all bids is expressly reserved by the Common Council.

All proposals should be endorsed "Proposals for Sewers."

JAMES T. MACMURRAY,
City Clerk.

ANDREW J. GAVETT,
Engineer-in-Charge.

U. S. ENGINEER OFFICE, 1637 INDIANA AVE., Chicago, Ill., June 28, 1902.—Sealed proposals for constructing foundations for five locks and one aqueduct bridge, the walls for eight locks, and the piers and abutments for five aqueduct bridges and one highway bridge, will be received here until noon, July 28, 1902, and then publicly opened. Information on application here or to Assistant Engineer L. L. WHEELER, Sterling, Ill. J. H. WILLARD, Maj., Engrs.

Additional Proposal Advertisements are printed on pages xv, xviii and xxvii.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Specialization in Engineering Education.

There is probably no question on which there is a greater variety or a greater number of opinions among practicing engineers, and possibly among engineering educators themselves, than in connection with the subject matter and methods in the professional engineering schools. Masses of papers and addresses and discussions of them have been published within the last ten or a dozen years bearing directly upon practically all features of engineering education, and yet there is probably not one of those features on which opinion is unanimous or anywhere near so. This is mainly due, obviously, to the rapid progress which has been made in all branches of engineering during that period. Indeed, so rapid has been the development and expansion of engineering specialties, and so urgent has been the demand for educated young men to take positions in those specialties that many engineering educators have endeavored to meet the requirements of the situation by extraordinarily specialized lines of engineering education. This specialization of educational training has led to courses in mechanical engineering, electrical engineering, hydraulic engineering, railroad engineering, and in almost numberless other "engineerings" characterized by great intensity of work along the special lines which they represent, which is another way of saying that these developments of educational training are more or less narrow in scope, and in some cases very narrow. These restricted courses of engineering study have, in some cases at least, been confined between such narrow limits as to detract most seriously from their professional value. Many engineering educators throughout the country have frequently publicly expressed their regrets at this extreme specialization, and have not hesitated to state in papers and discussions that it was likely to trench most injuriously not only upon the broad, educational value of the courses of study, but also upon the ultimate professional efficiency and standing of the young men so narrowly educated. While some practicing engineers have from time to time taken the same general view of the subject, it is only lately that this particular phase of engineering education has attracted much attention from the profession in general. It is markedly significant that some of the strongest expressions regarding these mooted questions have emanated from that portion of the broad field of civil engineering which is devoted to what is probably the most specialized work of the engineer, both in practice and in the professional schools, i. e., electrical engineering.

At the recent annual meeting of the American Institute of Electrical Engineers, the president, Mr. C. P. Steinmetz, made an address bristling with pointed references to this matter, which amounted in essence, if not in form, to emphatic disapproval of too much specialization. Among other things he states: "If, of the amount of material in electrical engineering as well as other branches which the educational institution of to-day attempts to teach, one-half or more would be dropped altogether, but the rest taught so as to be fully understood, with special reference to general principles and methods, the product of the institution would be far superior and more successful in practical life." Again: "Design of engineering apparatus is of very secondary utility and rather objectionable, with the exception, perhaps, of some very simple apparatus." Finally he states that the professional school should "give the student all the ground work required to be successful in future practice, but not the impossible aim of giving him a complete education as practical engineer." These quotations from Mr. Steinmetz's address go straight to the very pith and substance of the whole question of professional education. The function of the professional school, as he states, is not to attempt to make a finished practitioner, but to ground the young man especially in general principles of that which is too often disapprovingly called the theoretical work of the engineer, but in such a way as consistently to show its intimate relation to practical matters and how it is to be applied in the practical work of the engineer.

A number of other speakers at the same annual meeting criticized in an outspoken manner the dangers of too much specialization in the particular field of electrical engineering. Prof. Esty, of the University of Illinois, laid down the following general proposition: "Teach thoroughly those things which are fundamental; devote little time to highly specialized subjects; introduce the student to those branches of knowledge which in his later life he can acquire, if at all, only with increasing difficulty."

But one more quotation will be offered, although a considerable number of others might be made, and that from the address of Mr. H. W. Buck, electrical engineer of the Niagara Falls Power Company. He asserted "that many instances may be cited of men who have been prominent as electrical engineers who have been dropped out of place in the course of the rapid progress which has been made on account of lack of a theoretical foundation in their knowledge."

These are observations of unusual significance from the special field of electrical engineering; but views quite as strong upon the same general subject are held in other quarters, as illustrated by many papers which have appeared in the "Proceedings" of the Society for the Promotion of Engineering Education, one of the last of which is by Prof. Edgar Marburg, presented at the recent meeting in Pittsburg. His observations are quite pointed against too much specialization in civil engineering, and they are undoubtedly justified by the present tendency in many quarters.

It is a most serious question whether educators in engineering having charge of the professional courses in engineering study throughout the country should not carefully reflect upon these evidences of disapproval of too much specialization, both from the fields of practice and of education, and consider whether the intense specialization now being carried on among educators is not working damage both to the broad educational value of these specialized courses of study and to the future engineering work of the young men taking them. This specialization of professional study is not found in the law or medical schools of the country, although there is quite as much intensity of specialization in actual practice in both of those fields. Their courses of study, however, are much more wisely administered in this respect in that every student in law and medicine is obliged to pursue a broad and comprehensive professional course of educational training, giving him a familiarity with and a control of all the general principles underlying the practice of his profession in all of its specialties. The result is a course of study in the highest degree valuable, as such, endowing him with the best possible foundation for any special field of professional practice which he may subsequently desire to follow. The broadly educated specialist, other things being equal, is by far the best specialist; he attains that end both in consequence of a better knowledge of his own special field and of those lines of work affiliated with it; his grasp of general principles enables him to accomplish far more and to do it better than the narrowly educated man, and it will be but a short period after the beginning of his practice before he will outstrip him in every line of special work. While this is true of the specialist, it applies with greatly enhanced force to those engineers who fill administrative or executive positions requiring thorough knowledge of the fundamental principles of a number of affiliated specialties. Indeed, whether the specialist, the general practitioner or the executive engineer be considered, the broad, thorough course of educational training will qualify him for the greatest measure of success.

The Brooklyn-Manhattan Rapid Transit Railroad briefly described in this journal a fortnight ago will be built by the McDonald-Belmont syndicate. On Thursday the contract for the work was awarded to it by the Board of Rapid Transit Commissioners for $2,000,000, exclusive of $1,000,000 allowed for terminals by the Board, the only other bid received being one of $7,000,000 from a representative of the Brooklyn Rapid Transit Company. Mr. McDonald and his associates in the New York Rapid Transit Railroad contract have thus undertaken to construct for about a quarter or a fifth of its cost an underground and subaqueous route connecting the New York system with the heart of Brooklyn and with one of the terminals of the Long Island Railroad. They have also secured control of the underground route from the Post Office in Manhattan to the Battery, and they have acquired the rights to a route in Brooklyn which brings them into touch with a fairly comprehensive system of surface cars not controlled by the Brooklyn Rapid Transit Company. A few months ago they secured the control of a moribund corporation authorized to tunnel under the East River, and have resuscitated its dry bones into a skeleton of pretty sturdy appearance. They also have a scheme for extending their Bronx lines north to Port Chester, and they have offered to build for $1,100,000, less than half its cost, a subway under Broadway from Forty-second Street to Union Square.

Power Plant of the Berkshire Street Railway Co., Pittsfield, Mass.

The Berkshire Street Railway Company has now about completed near Pittsfield, Mass., an interesting power plant for the operation of its railway, a new electric trolley line extending from Cheshire to Great Barrington, a total distance of about 40 miles. The alternating-current method of power distribution, at 13,300 volts, will be used, distributing to three sub-stations, in all of which there will be rotary converters for supplying direct-current to the trolley wires. Two 750-kilowatt units are at present installed in the power station, direct connected to cross-compound condensing engines. Vertical twin jet condensers are employed, and for warming the constant indraft of feed water, and utilizing the heat in the exhaust steam, primary heaters are located in the main engine exhaust pipes and an auxiliary heater is arranged to receive the exhaust from all auxiliary machinery. The live-steam, exhaust and water piping is quite complete.

The station is a brick structure, built with the engine and boiler rooms side by side, the former 62x107 feet in plan and the latter 42x95 feet. It is located alongside the main line of the Boston & Albany Railroad, from which it has a siding for the delivery of coal, and is near a small stream from which it obtains both feed and condensing water. The engine room is 8 feet 8 inches above the floor of the boiler room and underneath the engine room is a basement, the floor of which is 12 feet below that of the engine room. Alongside the division wall it is depressed, to form a condenser pit, 5 feet 4 inches below the boiler room floor. In this are located the condensers and steam and water piping, including the primary heaters, leaving the engine room unobstructed in this respect. The auxiliary feed-water heater, together with the feed and circulating pumps, are in the boiler room, under ready control of the firemen.

The boiler equipment consists of four water-tube boilers built by the Aultman-Taylor Machinery Company, of Mansfield, O., set in two batteries, with space remaining for a third battery. The power house is situated considerably below the steam railroad tracks, and the coal is dumped from the railroad cars against the boiler house wall. The coal is taken through a door over a platform scale and carried to the firing places in 2,000-pound side-dumping cars, made by the Hosher Platt Company. The products of combustion are carried from the boiler into a brick chimney rising outside of and independent of the station building. This was erected by the Alphons Custodis Chimney Construction Company with its radial brick, and is 175 feet high and 8 feet in diameter at the top. Each boiler contains about 3,930 square feet of heating surface arranged in 4-inch tubes, in 16 sections, each 12 tubes high, and has 68 square feet of grate surface. Each boiler has two steam drums 42 inches in diameter and 20 feet 2 inches long. A steam pressure of 150 pounds is carried, and each boiler is rated to evaporate 11,800 pounds of water per hour.

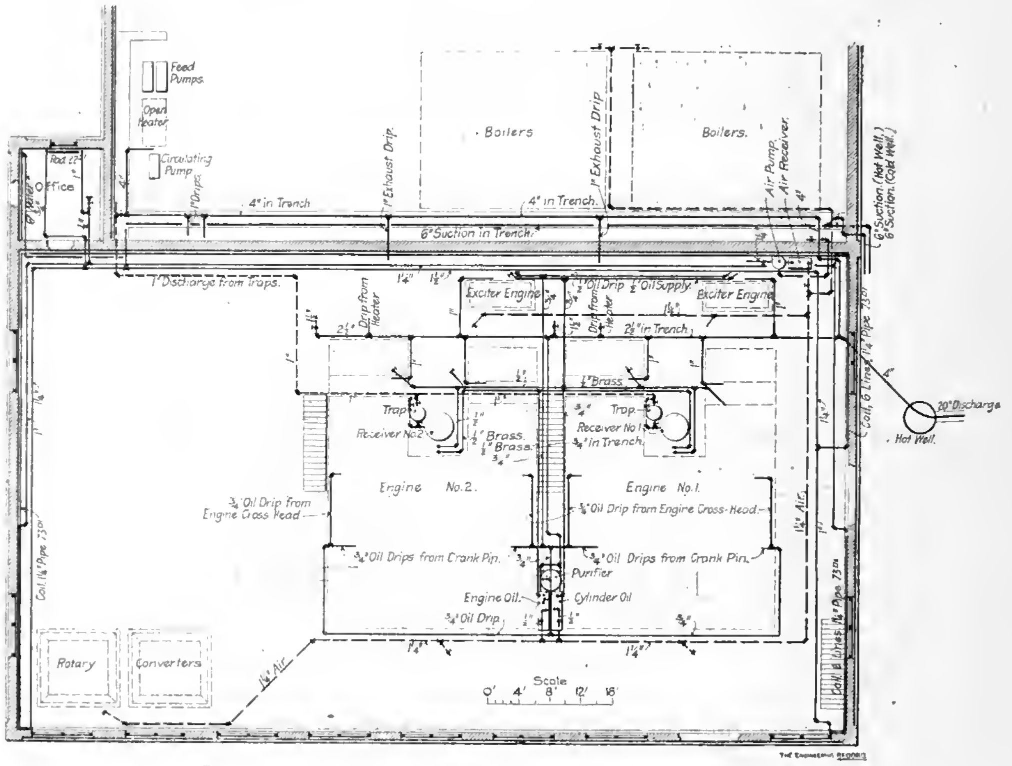
There are two steam mains or headers, one for the main units and the other for all the auxiliary machinery. For the supply of the main header each boiler is provided with an 8-inch connection starting from an automatic stop and check valve on the cross pipe connecting the two drums and bending horizontally, and then vertically downward to the header, where there is a gate valve about 8 feet above the floor level, controlling the boiler supply pipe. The header itself is about 6 feet above the floor, and connections from it to the engines are taken horizontally immediately below the basement ceiling. The header is 14 inches in diameter and each half may be operated independently. All the steam piping is extra strong, with Chapman valves and Crane fittings, the flange dimensions conforming to the schedule of extra heavy flanges, which were put into effect on January 1 of this year, according to agreement by many leading pipe manufacturers, as printed in The Engineering Record of October 12, 1901. Two thicknesses of thin Jenkins packing with corrugated copper between were used.

Each engine is supplied also by an 8-inch pipe, carried horizontally, as stated, from the main header, and has a Cochrane separator just before the steam is taken upward to the engine cylinder. As indicated in the accompanying drawings, the live steam can be fed, if necessary, to both cylinders of the engine, and, of course, to either of them, but in the branch leading to the low-pressure cylinder a Kieley reducing valve has been introduced, by means of which the mean effective pressure on the large piston of the low-pressure cylinder can be regulated throughout a considerable range. For the disposition of drips from the separators and condensation from the headers, an interesting adaptation of the Holly system of returning water to the boilers without pumping has been installed under the supervision of Westinghouse, Church, Kerr & Company. The drip lines are led in the usual way to a header, which is located in the condenser pit against the division wall, low enough to receive the water by gravity, and the water is drawn from the Holly header by a forcing tee which has a direct connection with the main steam header. A $1\frac{1}{2}$-inch riser carries the steam and entrained water to the condenser of the system, which is located on the roof of the boiler house, 37 feet above the boiler room floor. In addition to the condensation of steam taking place in this condenser by reason of its exposed position, a pipe fitted with a relief valve leads from the top of it to the auxiliary feed-water heater. A 3-inch return pipe carries the water to a 2-inch header extending across the front of the boilers for the return to the boilers of the water of condensation from the high-pressure steam lines.

The exhaust piping, as well as the live-steam piping, represents good modern practice, as already stated. The high-pressure cylinder exhausts into a receiver, or when the low-pressure cylinder is out of commission, into the main exhaust header. This header is 16 inches in diameter and toward each end feeds through a primary feed-water heater. It is arranged with valves so that, if necessary, the exhaust into one end can pass through the exhaust outlets corresponding to the other unit. The heaters, which are 1,000 horse-power Goubert horizontal feed-water heaters, having 333 square feet of heating surface each, are provided with the usual by-pass. Immediately beyond the heaters, the steam reaches the condensers, at which point is the relief valve allowing for the escape of steam when the condenser is not in operation. The condensers consist of vertical twin pumps and a jet condenser built by the Warren Steam Pump Company, of Warren, Mass. The pumps have twelve-inch steam cylinders, 30-inch water plunger and 18-inch stroke.

The generating units consist of Westinghouse alternators and Rice & Sargent engines built by the Providence Engineering Works, of Providence. The engines have 22 and 44-inch cylinders and 48-inch stroke and are operated at 94 revolutions per minute. The alternators are of the revolving field three-phase type and have a full load rating of 32.6 amperes per phase at 13,300 volts and 25 cycles per second. The generators are separately excited and for that purpose there are two 20-kilowatt 125-volt direct-connected Westinghouse units, employing $7\frac{1}{2}$x7-inch double-cylinder vertical Westinghouse steam engines. For the supply of the neighboring sections of the railroad, rotary converters are installed in one corner of the engine room, and for the distant sub-stations the current is transmitted directly from the alternators at 13,300 volts, being stepped down by banks of static transformers in the sub-stations to 380 volts alternating and converted by rotary converters to direct current at 660 volts.

For the supply of the exciter units and the various steam pumps, an auxiliary header has been provided, as mentioned. The steam connection from each boiler for this system is taken at the point where the safety valve is fitted, and the connections from each pair of

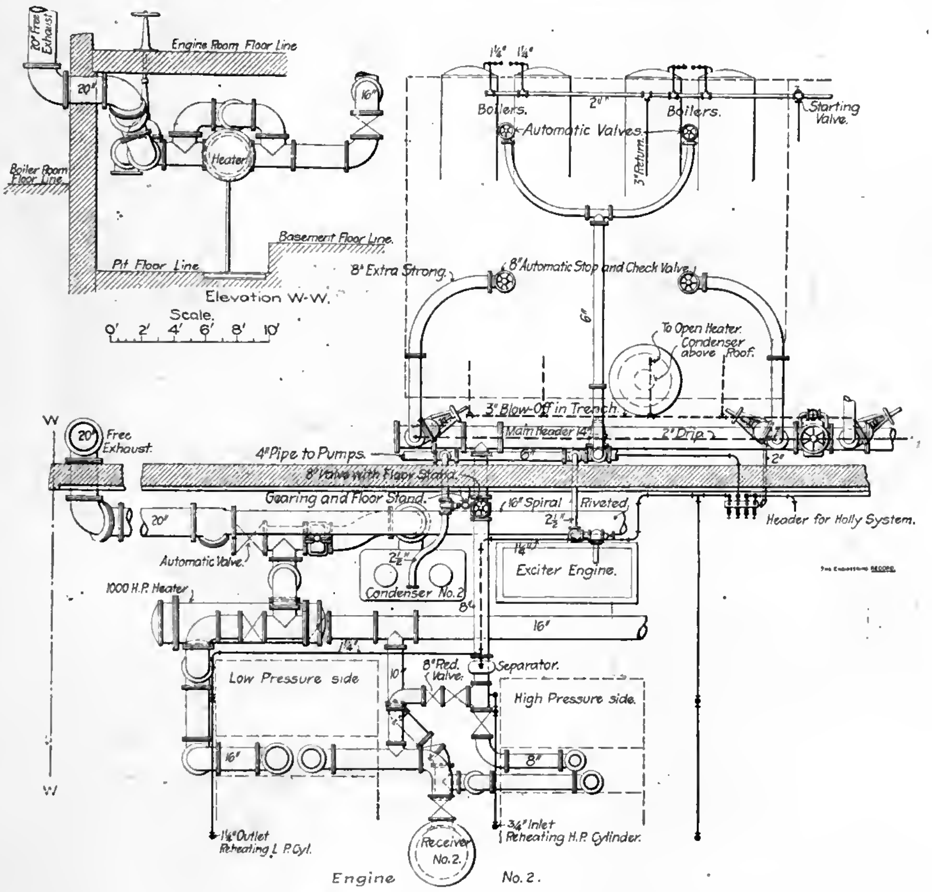


PLAN OF THE STATION, SHOWING DRIP, AIR AND OIL PIPING.

boilers is united and passes 6 inches in size to the header. The header is located just below the main header against the division wall. The connection from each boiler is fitted with an automatic valve at the boiler, and each battery is controlled by a gate valve immediately above the header. The branches to the various auxiliaries are taken from the top and no separators are used.

The supply of water for the plant is taken from the Housatonic River in the bed of which a stone well was sunk about 10 feet below bottom. Each condenser is provided with an independent suction pipe from this, of cast iron, 10 inches in diameter, and there is a 6-inch suction leading to the boiler-feed pumps in the boiler room. The latter is joined by a 6-inch pipe from a hot well, which is just outside the building, receiving the discharge from the condensers, each condenser having a 16-inch discharge, which has thus an area about 2.5 times that of the corresponding injection pipe, and the two discharge pipes uniting in one 20 inches in diameter. Near the pumps in the boiler room ceivers being provided with a trap for the purpose. The auxiliary exhaust is cross-connected with the main exhaust in the boiler room, with a valve in the cross-connection, so that when desired the main exhaust riser can be used to carry off the exhaust from the auxiliary plant or the exhaust from the main engines may be utilized in part in the auxiliary or secondary heater. The boiler-feed pumps can be controlled by means of an automatic valve inserted in a live-steam supply to them, the valve being actuated by the level of water in the heater.

Among the accessories of the plant is a system of compressed air pipes with five outlets distributed about the engine room, arranged for ¾-inch hose connections for cleaning purposes. The air is furnished at 70 pounds pressure by a Westinghouse compressor connected with a receiver. A system of lubricating oil pipes has also been installed, including an oil purifier, oil reservoirs, etc. The oil is distributed by air pressure furnished by the air pump above mentioned, the oil tanks being placed in the engine room basement. The en-



STEAM CONNECTIONS TO ENGINE NO. 2.

a 4-inch line carrying Pittsfield city water is connected into the 6-inch suction, so that the plant may receive water from both the hot and cold wells and the city mains. Ordinarily a 6x6x6-inch Warren duplex pump takes the water, discharges it in a 4-inch wrought-iron line to the primary heaters, and from them in a brass pipe, to the auxiliary feed-water heater, which is a 2,000 horse-power Cochrane combination open feed-water heater and purifier. From this the water is taken by either of two 10x6x12-inch Warren pumps, installed in duplicate, which feed to the boilers. The small or low-pressure pump can also discharge directly into the Cochrane heater and the boiler-feed pumps can also receive the water from the hot and cold wells and pump either directly into the boilers or through the primary heaters, and thence into the boilers. The open heater receives the steam from the exciter units and the steam pumps, and also the condensation from the heating system for the building and the drips from the engine receivers, each of the re-

gine room is spanned by a 15-ton hand-power traveling girder crane.

The plant was designed by Mr. Charles K. Stearns, of Boston, Mass., and the building was erected by Messrs. Dodge & Devanney, of Pittsfield.

The Hydraulic Dredge, "J. Israel Tarte," built last year for the Canadian Department of Public Works by the Polson Iron Works from the designs of Mr. A. W. Robinson, has been at work long enough to demonstrate its success. It has a steel hull 160 feet long, 42 feet wide and 12½ feet deep, and has a power plant of 1,500 horse-power. It was designed to excavate a channel through the blue clay deposits in the St. Lawrence between Montreal and Quebec, and can dredge to a depth of 50 feet, if necessary. The clay is broken up by a patented cutter, which feeds it into the suction pipe, the main pumps being used solely to transport the dredged material, for which purpose there is a 36-inch floating discharge pipe 2,000 feet long.

The "Rust Stains" From Water Containing Crenothrix.

The precipitation of iron from water has been for some time the cause of serious trouble in numerous cities which have taken their supplies from filtered or ground sources. This precipitation has usually been accompanied by a heavy growth in the water of the giant bacterium known as Crenothrix. Such was the case in 1878, when the Tegel water supply of Berlin became seriously contaminated by the precipitation of flocculent iron, and the wells sunk near Tegel Lake had to be abandoned as a source of supply. A similar precipitation of iron brought about the abandonment in 1887 of a set of sand filters which derived their water from the river Maas, at Rotterdam. During the last ten years this iron bacterium has caused serious trouble in numerous cities both in America and in Europe, and much expense has been involved in the replacing or treatment of the supplies affected. Immediate practical value is accordingly attached to a paper by Mr. Daniel D. Jackson on the precipitation of iron, manganese and aluminum by bacterial action, recently printed in the "Journal" of the Society of Chemical Industry, of which an abstract follows:

Crenothrix occurs chiefly in ground waters, and only grows with rapidity when the dissolved oxygen is lacking or nearly so, and when the special salts which it precipitates are present. The presence of much organic matter, the absence of light, and the presence of carbonic acid in the water are also usual conditions, and seem to favor the growth of the organism.

In many places this growth has occurred in driven-well tubes, and has either stopped up the tubes or has been carried on to clog the screens. If allowed to go through the well screens, it has made the waters disagreeable in appearance, and unfit for domestic use or for industrial purposes. It grows rapidly in the bottoms and sides of filter galleries and dug wells and in the dead ends of pipes where the oxygen dissolved in the water has been exhausted. Growth may also take place in the bottoms of ponds which have become stagnant.

Partially filtered surface waters are more subject to growths of Crenothrix than other waters, and the various ground waters follow next. The Crenothrix found in brooks and rivers usually comes originally from other sources, and is not natural to the streams themselves. Surface waters are comparatively free from the organism because the conditions for growth are not often found in such waters. The presence of Crenothrix in filtered water means improper conditions for filtration, leading to a reduction of the dissolved oxygen and causing conditions which would favor the reduction and solution of the metallic elements in the soil.

The growth of Crenothrix, wherever it occurs in water, causes a disagreeable turbidity which may be yellowish white, yellow, red, brown, or black. It may be stringy in appearance, but usually occurs in flocculent masses, which in time settle to the bottom of the bottle in which the water has been collected. Under the microscope these masses are shown to consist largely of an organic growth composed of long strings of bacteria inclosed in a gelatinous sheath, in which is imbedded the precipitated metallic hydrate.

There are three species of the genus Crenothrix. The common species, Crenothrix kühniana, precipitates iron hydrate, and is consequently red or reddish brown in appearance. The second is less common and less widely known among botanists and bacteriologists.

It was formerly known as Leptothrix ochracea, but is now more properly called Crenothrix ochracea. This species precipitates aluminum hydrate, and is yellow to yellowish white in appearance. Its usual color is that of ochre, as it nearly always precipitates some iron with the aluminum. The third species, Crenothrix manganifera, is rare in occurrence and has been found as yet in but two places, the Neponset River and the filter galleries which supply the city of Newton, Mass. It precipitates manganese hydrate, and is dark brown or black in appearance.

There are several points of interest chemically in the analyses of the materials precipitated by these three species. The analyses show that about one-third of the entire dried precipitate consists of the special oxide which the species throws down in the form of hydrate; another third or more consists of organic matter and is chiefly that which is the living portion of the organism; while the remainder, which may be merely accidental and not a true constituent, is largely silica and aluminum silicate.

Analyses of waters which contain Crenothrix show that they contain salts which especially favor the growth of the particular species which they propagate. For example, waters which produce Crenothrix kühniana contain a predominating amount of iron, while aluminum and manganese are the predominating metals in water containing the ochracea and manganifera species respectively.

The theoretical conclusions to be drawn from a study of this subject are:

(1) Each of the three species seems to use a selective power in precipitating the special oxide ascribed to it, and about one-third of its dry weight is composed of the oxide selected, whether it be of iron, manganese or aluminum.

(2) Crenothrix kühniana is very common, because iron in quantity is a common constituent of water; Crenothrix ochracea is rather uncommon, because aluminum sulphate or aluminum combined with carbonic acid and organic matter is uncommon in water; Crenothrix manganifera is very rare because manganese seldom occurs in sufficient quantity in water to produce any very noticeable growth of the organism.

(3) The growth of all three species is due to the lack of oxygen, with a consequent reducing action in the soil or water. This reducing action may be produced by stagnation in the bottoms of ponds or by improper or too rapid filtration in wells or filter galleries, thus causing the solution of iron, manganese or aluminum from the soil. These, combined with organic matter, seem to furnish the food material for the organisms, while the oxides of iron, manganese or aluminum which are precipitated in their gelatinous sheaths are the dross of the operation.

As practical suggestions leading to the prevention of the growth of the organism the following are offered:

(1) Keep the water of wells and filter galleries as thoroughly aerated as possible, and blow off the dead ends of pipes frequently when there is danger of the loss of dissolved oxygen. The Crenothrix in the latter case takes its iron from the pipes themselves.

(2) Avoid driving wells through large deposits of peaty matter.

(3) Avoid driving wells or filter galleries too close to the shores of ponds or streams having large deposits of organic matter on their banks.

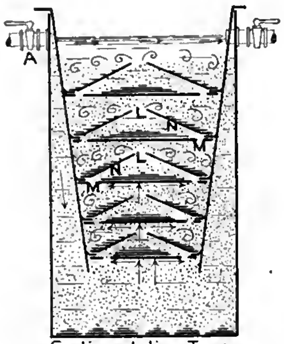
(4) Avoid pumping too heavily from any wells or filter galleries, as the conditions are often thus produced which are favorable to disastrous growths of Crenothrix.

Scrubbers for Preparing Water for Filtration.

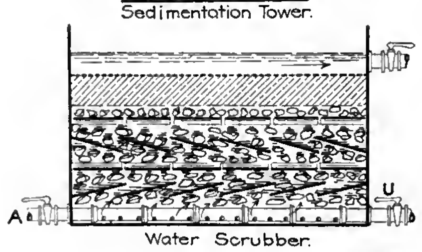
Abstract of a paper presented to the American Water-Works Association by Mr. P. A. Maignen, Assoc. Am. Soc. C. E.

More than twenty years ago the writer became convinced that however well plain sand filters might work at slow rates with a comparatively clear influent, they were unsuccessful when the applied water was dirty or the rate was high. His first plan was to protect the sand against mud by an artificial membrane serving as a substitute for the "schmutzdecke" of a natural filter, and this was found to be satisfactory except when the applied water was very roily. Settling ponds were considered undesirable on account of the growth of algae and fish in them, and decantation in long, narrow channels would not intercept the fine suspended matter. Recourse was therefore had to experience gained in removing the fine suspended carbonate of lime from water which had received a softening treatment.

The first principle which such experience establishes is that in decantation the shallower the stratum of water the more effective the work. The second principle is that the alternate expansion and contraction of the water-way will cause settling of solid matter. This is occasionally seen on a large scale below the piers of a bridge, where the material in suspension in the water in the narrowed channel at the piers is deposited lower down stream as sandbars when the velocity is checked in the more open channel. The third principle is that some other means than decantation must be employed to eliminate the lightest particles from water. This is shown in the separation of ores by washing them down a channel crossed by depressions or troughs varying in cross section, the smallest being at the top of the channel. In such an apparatus the material is sorted into several sizes, the largest pieces in the smallest trough, but there are nevertheless particles too light to be precipitated and these float away.



Sedimentation Tower.



Water Scrubber.

The Engineering Record.

The application of these principles requires an apparatus different from the common idea of a decanting tank. The latter has usually a series of vertical or inclined baffle plates and the water passes alternately below and above them. In this arrangement there may be a few small nooks where a little sediment can settle, but as the velocity of the water is practically the same throughout its passage there is no reason why more sedimentation should occur in one place than another.

In the sedimentation tower devised by the writer the principles outlined above have been applied so as to avoid the defects of the usual type of construction. The water enters at A, in the diagram, descends as shown by the arrows, and then rises through a nest of cones. The bottom of each cone has ¾-inch holes arranged around its periphery and an opening of 2 or 3 inches in the apex. The bottom and conical plates have a rubber gasket at their joint. The water strikes the horizontal base of the cone, travels sideways to the holes M, follows the inclined surface NL and then emerges from the hole in the apex.

A modification of this same idea is employed in the scrubber for the preparation of water for filtration and in general to separate matters in suspension from the liquids in which they are held. Instead of the expensive metal cone, only applicable to small apparatus, plates or slates are arranged as shown in the diagram and the intervening space filled with broken stone, slag or coke, not less than 1½ inches in size. The water entering at A rises through these obstacles, which cause it to flow in various directions, sometimes throttling it and at other times allowing room for eddies and sedimentation. There also seems to be some sort of attraction exerted by the large particles on those of smaller size. When the accumulation of sediment is sufficient to interfere with the working of the scrubber, the valve U is opened and the deposits flushed out. The very light particles which would either choke a sand filter or go through it are intercepted by an elastic layer of sponge, peat or excelsior on the top of the scrubber.

Some of the results attained with these scrubbers are shown by the following figures:

Scrubber A was operated from September 5 to November 16, 1901, at an average rate of 63,000,000 gallons per acre daily, during which time the (silica) turbidity was reduced from 15.4 to 2.8, or 78.3 per cent., and the bacteria from 3,088 to 175, or 98 per cent. More detailed figures of other runs are given in the accompanying table.

Results Obtained with Scrubber A in 1901.

From	April 25	June 6	Aug. 8
To	June 5	Aug. 8	Aug. 28
No. of days	41	63	20
Rate; mil. gals.	57	66	64
Turbidity, before	31	18	16
" after	10	4	6
" removal, per cent.	68	78	63
Bacteria, before	3,700	1,800	2,000
" after	400	180	180
" removal, per cent.	89	90	91

Scrubber B, during a run from September 13 to November 16 at an average rate of 64,600,000 gallons, reduced the turbidity from 13 to 1.09, 93 per cent., and the bacteria from 3,117 to 131, 95 per cent.

Scrubber D was operated for a time at the rate of 123,000,000 gallons, and at this high rate the turbidity was reduced on an average from 18.4 to 2.9, 84 per cent., and the bacteria from 2,042 to 181, 91.1 per cent.

An examination of the results with these scrubbers, all working with a loss of head not exceeding 2 feet, shows a constantly high removal of the bacteria owing to some function of the apparatus not yet clearly understood. It may be biological or physical or both; all that can be done now is to call attention to the fact and leave its explanation to be determined by further investigation.

An Aerial Tramway 4,200 feet long and having a difference in elevation of 2,100 feet between terminals has been built at Deep Gulch, Colo., for the American Gold Mining Company by the A. Leschen & Sons Rope Company. There are two supporting cables, one of 1⅛ inches diameter for the loaded buckets to come down on, and the other of 1-inch for the empties; the endless hauling rope is ¾-inch. The tramway carries both men, supplies and ore.

Self-Purification in the Sudbury River.

Abstract of a paper by A. G. Woodman, C. E. A. Winslow and Paul Hansen in the "Technology Quarterly" for June.

The Sudbury River, in the eastern part of Massachusetts, furnishes, in some respects, a particularly favorable opportunity for the study of self-purification. Of its total watershed of 164 square miles, the upper portion, including 94 square miles of steep and hilly country, is used as the source of part of the water supply for the Metropolitan District of Boston. The Legislative Act under which this water privilege was granted provided that 1,500,000 gallons of water per day should be allowed to flow past the lowest point at which water was taken by the city; and in dry weather the flow of the river immediately below scarcely exceeds this amount. From the reservoir of the Metropolitan Water-works to the village of Saxonville, the stream is practically unpolluted, except at times of very heavy rain. At Saxonville it is dammed to furnish power for the Saxonville Mills, and from the mill grounds it flows off, heavily charged with manufacturing wastes. Measurements of these waste liquors, made by the Massachusetts State Board of Health in 1900 and 1901, showed their amount to be 30,000 gallons per day, and this may now have increased somewhat on account of enlargements in the mills. The wastes, when studied by the Board, were made up of about 21,000 gallons of wool-scouring liquor, 7,000 gallons of dye liquor, and 2,000 gallons of yarn-washing liquor.

Besides the manufacturing wastes from the mills, a certain small amount of domestic sewage probably enters the river from the village of Saxonville. Below the village, however, beyond Station 10, the stream flows for 16 miles to the town of Concord without any appreciable additional pollution. For the first 3 miles below Saxonville it runs rather rapidly, in places perhaps at a rate above 2 miles per hour. Beyond Station 9 the river enters the Wayland and Sudbury meadows, and for the rest of its course winds sluggishly along through a weedy channel with a speed of not over ¼ mile per hour. There are no dwellings, with the exception of half a dozen summer camps in the proximity of the river, in all this distance; and it is entered by only a few small tributary brooks.

We have, then, in the Sudbury River, during the dry season, a small stream polluted at a single point to an extent of about 2 per cent. of its total volume by a liquid three to five times as strong as ordinary city sewage. For 16 miles below this point no additional pollution enters, and (at times of low water) comparatively little dilution occurs. For most of this distance the flow is very sluggish, and the conditions of self-purification decidedly favorable. The report of the Massachusetts State Board of Health upon the sanitary condition of the Sudbury and Concord Rivers, May, 1901, contains analyses of samples taken from seven points between Saxonville and Concord on August 15, 1900, from eight points on August 29, 1900, and from five points on February 27, 1901. In general, these analyses showed a marked purification; and in commenting upon them the engineer of the Board noted that near the outlet of Hurd's Pond, 4 miles below the Saxonville dam, half the pollution as measured by free and albuminoid ammonia disappeared, and that at Canal Bridge, 7½ miles below the dam, practically all evidence of pollution was removed. No bacteriological analyses, and no determinations of dissolved oxygen, were made upon these samples. The object of the present investigation was to extend the study of the State Board of Health by making complete chemical and bacteriological analyses of a more extended series of samples taken at the time of minimum flow of the stream, when the conditions for the study of self-purification are most favorable.

All field-work and collection of samples has been done by Messrs. Winslow and Hansen; all chemical work by Mr. Woodman; and all bacteriological work by Mr. Winslow. For the conclusions the authors are alike responsible.

The first set of samples, ten in number, were collected October 25, 1901, the first sample, at Concord, being taken at 11 A. M., and the last, above the Saxonville dam, about 8 P. M. Station 1 was about 16 miles below the dam and just above the first houses of the town of Concord; Station 2 was at the outlet, and Station 3 at the inlet, of Fairhaven Bay, the only considerable pond on this part of the stream; Stations 4 to 7 were at points 2 or 3 miles apart in the course of the stream through the meadows; no sample was taken at Station 8 on this first day; Stations 9 and 10 were at bridges, respectively 2.7 miles and 3,000 feet below the Saxonville dam; no sample was taken on this day at Station 11, 150 feet below the entrance of the raceway from the mill; Station 12 was in the mill-pond, just above the dam. One week later, November 1, a second set of samples was taken, covering all the twelve stations, but in the inverse order, beginning at Saxonville at 9 A. M. and ending at Concord at 5 P. M. The weather on both days was clear, except for a shower in the afternoon of November 1, beginning about 3 P. M.; and for several weeks previously there had been very little rain. The temperature of the water was taken on the second day and varied only between 11 and 12 degrees Centigrade, except at Station 11, just below the mill, where it was 18 degrees. It was not possible to make measurements either of the amount of water flowing in the river or of the velocity. As regards the latter point, however, it is certain that ¼ mile per hour would be an outside estimate of the speed below Station 8. At each station three samples were taken, one for bacteriological analysis, one for chemical analysis, and one for the determination of the dissolved oxygen; and each sample was collected in three portions, from each side and from the center of the stream. Inspection at the time of taking the samples showed the existence of pollution evident to the eye above Station 6, but no farther down the river. At Station 11 the stream, which had almost all passed through the mill, was highly discolored with dye liquor and very offensive. At Station 10 the milky look had somewhat disappeared, but the water was obviously foul; and between this point and Station 9 the stream flowed swiftly over a bed of rocks largely overgrown with Leptomitus, or some other sewage fungus. Between Stations 9 and 7 the speed of the river slackened, and an opportunity was furnished for sedimentation. At Station 6 the last ocular evidence of contamination was noticed, consisting of a considerable amount of flocculent suspended material in the water.

The analysis of the bacterial samples was begun on the evening of collection. Gelatin plates were made in duplicate and kept at room temperature, and agar plates were made and incubated at 37 degrees to give some idea of the proportion of thermophiles present. The agar plates were counted after 18 hours, the gelatin plates after 60 hours. Four or five portions of each sample were incubated in dextrose broth to determine the presence of bacillus coli. In the first set of samples portions of 1 cubic centimeter, 1/10, 1/100, and 1/1000, and in the polluted portions of the river, of 1/10000 cubic centimeter were used. In the second set of samples, a definite portion was selected for each station, 1/100 for Stations 10 and 11, 1/10 for Stations 8 and 9, and 1 cubic centimeter for the other points, and five duplicate tubes were inoculated. From the tubes showing fermentation of dextrose, litmus-lactose-agar plates were made; and if red colonies appeared, three were fished from each plate and subcultures made. Only those organisms giving typical reactions in dextrose broth, milk, nitrate solution and peptone solution, in the gelatin stab and on the agar streak, were considered to be colon bacilli.

The methods of chemical analysis followed were in the main similar to those employed in the systematic examination of water supplies by the Massachusetts State Board of Health. They are quite fully described in published reports of the Board, and it will be necessary to mention specifically only a few minor points.

The chemical analysis was begun on the morning following the collection of the samples. A portion of the sample was filtered through washed Swedish filter paper, and the filtered water was used for the determination of residue on evaporation, oxygen consumed, and color. The albuminoid ammonia was determined on both the filtered and unfiltered water, thus giving the amount in solution and suspension.

Color was determined by comparison with natural water standards, and is expressed in terms of the standard ammonia solution. Nitrites were estimated by Ilosvay's modification of the Griess method after decolorization with milk of alumina. Oxygen consumed was determined by Kubel's hot acid method, adding the reagents cold and boiling for five minutes. Oxygen dissolved was determined by Winkler's method on special samples collected at the same time as the samples for the main analysis.

In a general way, the pollution was not so great with the set of samples collected on October 25 as with the set of November 1; however, this apparent difference is partly due to the absence, in the first set, of a sample for Station 11, where the pollution would naturally be expected to be at its maximum. Another striking feature is the absence of the factor which usually proves the most valuable indicator of pollution, the free ammonia. This is no doubt due to the peculiar nature of the contaminating material, one entirely different from house sewage, in that it decays only slowly. For this reason this particular case is in some ways better, in some ways worse, than might have been desired. On the one hand, a factor usually relied upon for convicting evidence is removed; on the other, the changes taking place in such material are probably more prolonged than those which affect domestic sewage, and are therefore more readily followed and studied. Further, the Saxonville sewage did not very notably increase the chlorine content of the water, the nitrogen present as nitrites, or the organic matter oxidized by potassium permanganate.

The albuminoid ammonia curves show a rise on both days, with a maximum at the station nearest the mill. From this point the amount of albuminoid ammonia decreases gradually, the last point at which an excess is noted being Station 7. The "suspended" albuminoid ammonia drops still more quickly, and shows a more regular change, a fact due, no doubt, to the direct and constant influence of sedimentation, assisted possibly by the filtering effect of weeds or sedges. The residue and hardness show a somewhat similar relation, with the important difference that the fixed residue and hardness do not return quite to the normal in the whole length of the river, being perhaps added to by leakage of ground water along the course of the river. The very marked excess on the second day, however, disappeared below Station 8.

The irregular fluctuations of the nitrates are somewhat hard to understand. The rise at Station 10, with a subsequent decrease, is evident in both curves; and the fall at Station 11, on the second day, is interesting as suggesting a reduction of the nitrate normally present in the water. The dissolved oxygen shows the pollution and self-purification very clearly. A strong decrease on November 1, and a slight decrease on October 25, are followed by a gradual rise, reaching the normal between Stations 6 and 7, this region seems to be the crucial point of the chemical purification.

Bacteria per Cubic Centimeter.

Station.	Series I, Oct. 25. Gelatin, 20 deg.	Series I, Oct. 25. Agar, 37 deg.	Series II, Nov. 1. Gelatin, 20 deg.	Series II, Nov. 1. Agar, 37 deg.
1	180	46	170	18
2	300	33	390	29
3	770	36	720	29
4	4,230	27	1,320	37
5	6,400	44	1,390	39
6	8,100	70	1,900	72
7	7,100	130	2,900	71
8	.....	.....	4,600	43
9	17,000	610	73,000	870
10	6,000	1,400	33,000	4,300
11	.....	.....	150,000	8,200
12	320	22	160	455

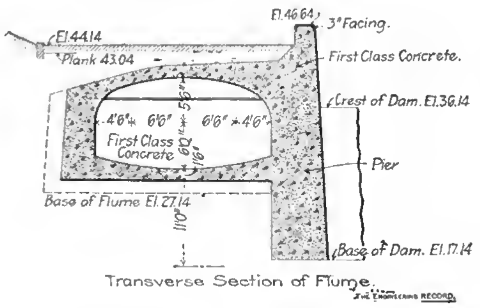
The results of the bacteriological analysis are very instructive. The total number of bacteria present in the water, as determined by growth on gelatin at 20 degrees, rose from one or two hundred to many thousand; a comparison of the figures for Stations 9 and 10 on the two dates showing, as do the chemical results, that the pollution was much greater on November 1 than on October 25. That the fact that on both occasions Station 10 gave lower numbers than Station 9, may be due to the fact that a small spring feeds the river at the former place. The pollution, as measured by the bacteria, is evident as far down as Station 3, considerably below the point at which the chemical purification appears to be complete. The thermophiles, as measured by the growth on agar at 37 degrees, show a similar increase, but their disappearance in the river is more rapid, the numbers reaching about their normal values at Station 6 on the first day, and at Station 8 on the second. The examination of the samples for the colon bacillus, on the first day, showed that organism to be present in 1/100 cubic centimeter at Station 10, and in 1 cubic centimeter below that point to Station 6. At Station 5 it happened that it was isolated from 1/10 cubic centimeter and not from the whole cubic centimeter examined; below that point it was not found. On the second day a certain dilution was chosen, and five duplicate samples examined. Bacillus coli was present four times out of five in 1/100 cubic centimeter, at Station 11, but not at all in that quantity at Station 10. It was found in a majority of cases in 1/10 cubic centimeters at Station 8 and 9. It appeared in a large majority of the single cubic centimeters examined from Stations 5, 6 and 7; in two cases out of five at Station 4, and in one case out of five at Station 2; not at all at Stations 1 and 3.

To summarize: The sewage of the Saxonville Mills, on the days observed, introduced into the Sudbury River a considerable amount of nitrogenous matter in the form of albuminoid ammonia, a considerable amount of mineral matter appearing mainly as fixed residue and hardness, and great numbers of bacteria, many of them thermophiles with some intestinal bacilli. During the 6 miles between Stations 11 and 7, organic pollution decreased and practically disappeared, at first rapidly, later more gradually. The thermophilous bacteria were removed during the same period. The total number of bacteria present was also greatly reduced, but remained distinctly above the normal during the sluggish flow of the stream to Station 4, 4 miles below. The colon bacillus also persisted in appreciable numbers down to Station 4.

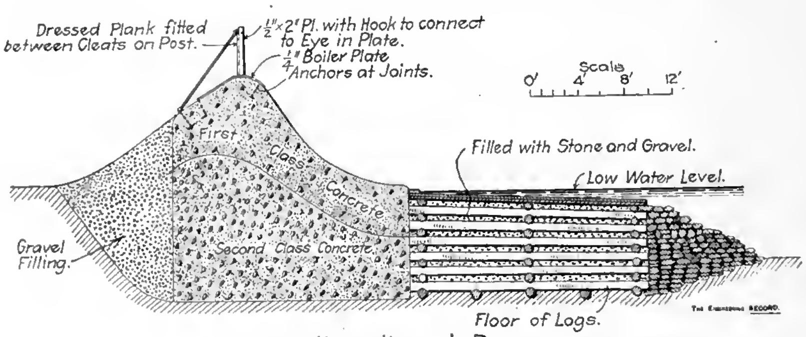
It appears, then, that under certain conditions bacteria, and even intestinal bacteria, may persist in a stream after self-purification from organic material has been effected; and that they may be found, even in a very sluggish stream, at a distance of 10 miles below their point of entrance.

A Concrete Dam Near London, Ontario.

The construction of a concrete dam across the Thames River at Springbank, Ontario, is described in a paper by Mr. J. A. Heaman, recently read before the Canadian Society of Civil Engineers. The dam furnishes power for the London water-works, and was built to replace a timber cribwork and pile structure which had been washed out. The latter was built in 1878 and needed constant attention to keep it safe and watertight. In the spring an ice jam usually occurs at a railroad bridge a few miles above the dam, and the failure of the old dam is ascribed to large cakes of ice



Transverse Section of Flume.



Section through Dam.

coming down from this jam when the water was not sufficiently high to carry them clear of the dam. These cakes gradually loosened the planking of the cribwork and the filling then washed out, after which the piles were either broken or washed away.

The new dam is about 350 feet long and about 19 feet in height above the foundation, which is a clay hardpan, except in one place where a vein of loose gravel was consolidated by ramming dry concrete into it. The dam was built in sections about 50 feet long with joints of sheet iron covered with a coating of sand and pitch to allow for expansion and contraction. It was built of the heavy section shown in the illustration because of the danger from ice in the spring. The first class concrete, which was used in the exposed part of the work consisted of 1 part of Portland cement, 3 parts sand, 4 parts screened gravel and 2 parts broken stone. Second class concrete was of the proportions 1:3:5:3. In the second class concrete stones averaging 9 inches in diameter were set by hand as the work progressed. The outside faces of the concrete were carefully floated with steel trowels before permanent setting had taken place.

By means of flashboards the water can be raised to a height of 4 feet above the crest of the dam, and it is stated that these flashboards can be put in position with 9 inches of water going over the crest. The sluiceway, which is at the further end of the dam from the flume and wheelpit, is about 7 feet lower than the dam. The sluiceway is in two parts, each 24 feet wide and separated by a concrete pier 6 feet thick at the top. Stop logs 12 inches square are used to raise the crest of the spillway to any desired level. Below the dam a timber apron was constructed of round timber, green pine and elm being used for this purpose. The logs were framed, notched and gained together, drift-bolted at all intersections and through-bolted at ends of timber, with ¾ inch bolts. Timbers running across stream were not less than 24 feet long, and were laid so as to break joint. The other timbers were in one length, and drift bolts of ¾ inch square iron were driven through three timbers on every course. The last row of sleepers or covering sills were flattened to grade lines to receive the two thicknesses of 2-inch elm planking. Below the apron a filling of stone, hand placed and bonded, was put in.

During the construction of the dam, although the season was favorable for operations on the Thames River, the contractor suffered considerable loss by repeated failures of his cofferdams and temporary works. The main cofferdam consisted of two thicknesses of 2-inch sheet piling resting against a framework of two rows of piles cross-braced together and further reinforced by long diagonal piles braced against the top of the sheet piling. In the deepest portions the two rows of piles were replaced with stone-filled cribwork. On the water side of the sheet piling were placed two rows of barrels filled with sand. The piles and sheet piling were nearly all driven by a heavy maul operated by hand. The inadequacy of this construction was frequently shown by a portion of the dam washing away.

The concrete arched flume carrying the water to the wheelpit is about 75 feet long, and has a section shown in the accompanying cut. Nearly 250 feet of concrete retaining wall was built at the same time with the dam. It is estimated that 3,541 cubic yards of first class concrete were laid at $5.50 per yard, and 2,605 cubic yards of second class concrete at $5.00 per yard. The cost of the whole work was $44,050. Mr. John M. Moore was the engineer in charge of construction, with Mr. John Kennedy as consulting engineer.

The Belated Publication of Municipal Reports has probably never been equalled by the record recently made by the city of New York. In the official journal of that city for July 21 there has just been printed the report of the commissioner of public works, General Collis, for the last quarter of 1897. Another New York document that should have appeared long ago but has not is the Water Bureau report for 1901.

Improvement of the Mersey and Irwell Rivers, England.

The purification of trade wastes which has been effected through the efforts of the Mersey & Irwell Joint Committee, organized ten years ago in order to prevent the serious pollution of those rivers, is a matter of considerable interest to sanitary engineers in this country as well as abroad, particularly as an example of some features of a system of river control suggested at the Washington convention of the American Society of Civil Engineers. In the recently issued report of Mr. R. A. Tatton, M. Inst. C. E., chief inspector of the committee, the present condition of the watershed is clearly presented. Of a total of 445 manufacturing establishments where purification works are necessary, 294 have efficient sewage treatment plants, 139 have plants not regarded by Mr. Tatton as efficient, 5 have works being constructed and 7 have adopted no method of treatment, in which the last class two years ago there were 17. It is stated that among those works not regarded as efficient there are many where the surroundings are too limited to allow of an efficient plant being installed. Of the 294 establishments having efficient disposal plants there are 84 dye works, 54 bleach works, 44 woolen mills, 37 print works, 18 paper works, 14 chemical works and a smaller number of industries of other classes. In addition to these 445 works there are about 250 more, which drain into public sewers and the waste waters of which are dealt with by the local authorities.

Of the 94 local authorities on the watershed, having a total population of over 2,450,000, there are 86 which have sewage disposal works in operation, 3 have works under construction, 2 are taking preparatory steps and only 3 have no scheme whatever under consideration. The various methods of treatment adopted by these local authorities is given in a voluminous table at the end of the report, which contains many interesting data. The system adopted in most cases is chemical precipitation followed by intermittent and in some cases continuous filtration through cinders, gravel or other comparatively coarse material. The precipitant most generally used is alumino-ferric. Lime and sulphate of iron are used to some extent, and in several cases settling tanks are used without any precipitant. The sludge from the precipitation tanks is in most cases pressed and disposed of to farmers. In a number of cases a septic tank and contact bed system is used, and it is stated that "biological treatment is being adopted more and more, and is of great value where suitable land [for intermittent filtration] cannot be obtained."

That manufacturers now generally recognize the necessity of treating their trade waste is shown by the fact that for the last four years it has not been found necessary to take any legal proceedings against them. However, it is stated that it continues to be a grievance on the part of the manufacturers of this watershed that similar progress is not being made with the purification of the rivers in other parts of the country. The question of creating a separate commission, or a new department of the Local Government Board, which shall have final authority in matters relating to rivers and their purification throughout the whole country is now being agitated.

The results of the ten years' work of the Committee is summed up by Mr. Tatton as follows: "As to the condition of the rivers generally, we must admit that considerable improvement has been brought about, but yet there still remains much to be done, and more especially by the sanitary authorities. Pollution of solid matter is, to a great extent, kept out of the rivers, but serious pollution is caused by the soluble putrescible organic matters which give rise to offensive emanations in warm and dry weather. Half measures for the purification of sewage are of little or no use. In fact, a partially treated sewage, which has perhaps been held up for some hours in tanks, and in which decomposition has advanced to some considerable extent, will cause more nuisance in the upper reaches of the stream into which it is discharged even than raw sewage in which the advanced stages of decomposition will not be reached until it has been diluted and brought into contact with the larger volume of the main rivers."

The Westchester Avenue Rolling Bridge, New York.

The new bridge over the Bronx River in the Borough of the Bronx, New York, is a low-level movable highway span with a timber trestle approach and is built on the site of an old bridge. It is a single-span deck-girder structure 60 feet wide over all, including two 10-foot sidewalks, and its axis makes a considerable angle with the parallel abutments, which are 40 feet apart in the clear. One end of the bridge is parallel with the abutments, but the other end makes an angle with them and extends in shore from one abutment, so as to allow the structure to be supported on trucks traveling on tracks parallel with this end, as shown in the plan. This gives a length of about 150 feet to the long side and about 60 feet to the short side of the bridge platform. The bridge moves on its rollers about 50 feet in a direction oblique to its axis, so that the sides of the platform move parallel to themselves and the bridge in opening recedes from one bank until the end is withdrawn from one abutment, completely across the channel to a position at the opposite end of the other abutment.

The substructure is unusually extensive for a bridge with such a short span and consists of two abutments and their curved wing walls, a long pier wall for one track and separate piers for the columns supporting the other tracks. The abutments are faced with coursed ashlar and the cap stones and coping are of cut stone; all the rest of the masonry is of Portland cement concrete and all footings are carried down to solid rock. This construction included about 5,000 cubic yards of earth excavation with sheet piling, pumping and back filling, 1,000 yards of rock excavation, 1,000 yards of earth filling, 4,500 yards of concrete, 650 yards of ashlar masonry and 3,600 cubic feet of coping, cap stones and bridge seats. The west abutment is 17½ feet thick at the base, about 45 feet high above the footing and 24 feet high above water level; the east abutment is not as large. Both of them are protected from collision with boats by three lines of horizontal 10x12-inch white oak fenders 72 feet long bolted to the face of the masonry above and below water line. The track columns are seated on concrete piers 55 inches square with cap stones secured by four long anchor bolts which extend down to bearing plates bedded two or three feet deep in the concrete.

The principal members of the platform are three longitudinal plate girders 20 feet 8 inches apart, two oblique end plate girders, nine lines of transverse lattice girder floorbeams 14 feet 10½ inches apart and perpendicular to the longitudinal girders, two fascia plate girders, fourteen longitudinal lines of 12-inch I-beam roadway stringers parallel to the main girders and about 3 feet apart, and two sets of horizontal lateral angles connecting both top and bottom flanges of the main girders and floorbeams.

One of the longitudinal girders is on the center line of the bridge, and the others are nearly under the curbs between the roadway and sidewalks; their lengths are respectively about 74½ feet, 105 feet and 135½ feet. The webs are 60x⅜-inch plates; the flanges are pairs of 6x6x⅝-inch angles and 14-inch cover plates; the web stiffeners, about 5 feet apart, are pairs of 3½x3½-inch angles with fillers, every third stiffener being a double pair of angles. The web splices are made with double cover plates with six vertical rows of field rivets. The flange splices are made with pairs of cover angles and single cover plates. The rear end girder E is about 85 feet long and has a ⅜-inch web plate 6 feet deep and a single angle in each flange. The tops of the roadway stringers are flush with the top flange and are seated on a continuous shelf angle. End girder D is similar to E, but is only about 67 feet long and 4 feet deep and has single 4x4-inch flange angles. Both end girders are web-connected to the longitudinal girders with field-riveted bent plates as shown in cross-section in one of the detail illustrations.

The floorbeams are lattice girders, as shown in the sectional elevation, and are made in four sections each, one section under each side of the roadway and one section under each sidewalk. The two middle sections are field-riveted at both ends to the vertical web stiffeners of the longitudinal girders and are about 5 feet deep at the center of the bridge and about 5 inches shallower at the curb, making the top flange inclined so as to conform to the crown in the roadway. The sidewalk girders are cantilevers riveted to the tops and bottoms of the vertical web stiffener angles of the longitudinal girders. The top flange of the floorbeam is parallel to the chord of the curve of the crown of the pavement and carries across it the longitudinal stringers, of uniform depth. In order to make the heights of the stringers conform to the ordinates of the curve those intermediate between the center line and the curve are seated on filler plates varying from 5/16-inch to 11/16-inch in thickness. The sidewalks have longitudinal 3x10-inch wooden joists overlapping on the top flange of the cantilever brackets, to which they are secured by horizontal bolts through the vertical flanges of short connection angles riveted across it. The top flange is about 2 inches higher at the outer end than it is at the curb so as to give the sidewalk the required pitch towards the curb.

The steel curb has a Z-bar with one horizontal flange riveted to the top flange of the longitudinal girder and the other one supporting the ends of the roadway planks. To the vertical web is riveted a face plate which protects the sidewalk joist and is finished on top with a 2½-inch half-round piece of steel riveted on. The fascia girder has a ⅜x22-inch web plate and one 3½x3½-inch angle for the lower flange and one 5x3½-inch angle for the upper flange. The web is riveted to the insides of the flanges of the angles and the horizontal flanges project towards the center of the bridge, enclosing the ends of the brackets and the edges of the sidewalk floor.

When closed the forward end of the bridge is supported on three roller bearings at the ends of the longitudinal girders, under end girder D, and the rear part is supported on seven four-wheel trucks under the longitudinal girders at their intersections with the track girders in the positions marked R, R, in the general diagram. When the bridge is opened the roller bearings are removed and the end of the bridge from the forward rollers, R, R, R, to girder D is a cantilever counterweighted by the rear part of the platform. To increase the stability a solid steel plate floor is supported on the lower flanges of girders A and E near their intersection, and by longitudinal girders which form sides of a sort of open box in which 95,000 pounds of cast-iron ballast are carried.

The abutment rollers are mounted in cast-iron frames anchor-bolted to the masonry as shown in the illustration, and engage tapered base plates bolted to the bottom flanges of the longitudinal girders so that when the bridge closes it is lifted slightly and throws a portion of the weight on the abutment, and the girders change from cantilevers to regular spans for all live load and a part of the dead load stresses. The trucks, as shown in another illustration, have solid cast frames bushed to receive the roller bearings of the axles, which are shouldered out at the ends where they are keyed to the wheels. A swivel bearing with the longitudinal girder is made by a vertical cylindrical seat projecting from the top of the truck to engage the cap plate, which is bolted to the bottom flange of the girder. The illustration shows the trucks under the rear ends of the girders where the rails are supported on masonry piers; the rails under the other trucks are carried by elevated track girders. These girders have double webs 24 inches deep and 26 inches apart, which at every vertical web stiffener angle are connected by vertical transverse diaphragm plates. Each web has a T-shaped bottom flange and an L-shaped top flange, the horizontal flanges of both the top flange angles being turned out and the flange of the inside angle resting on top of the flange of the outside angle and forming a smooth track for the truck wheel. At the shore ends of the girders the web plates project on the upper sides to form stops for the truck wheels. At the river ends cast-iron stop blocks are bolted to the top flanges, and cast-iron clamps are bolted to both ends of the rails, which are laid on the longitudinal pier.

The total weight of the structural steel is about 352,000 pounds, and the machinery weighs about 50,000 pounds. The bridge is very simply operated by means of a fixed 1-inch horizontal steel rope parallel and adjacent to track girder G and attached to it with clevises and screw adjustments at both ends. The cable takes one turn around a grooved drum which is operated by a 25-horse-power electric motor and moves the bridge forwards or backwards according as the drum is driven ahead or reversed. The drum is controlled by a band brake with a counterweighted lever and a system of cranks and links for its operation from the bridge platform above. The driving shaft is also geared to a mechanism by which it can be operated by hand.

The bridge was designed by the Department of Bridges of the city of New York while Mr. John L. Shea was commissioner and Mr. S. R. Probasco was chief engineer. Its construction was commenced under the direction of Mr. Gustave Lindenthal, commissioner. Mr. John G. Tait, New York, is the general contractor; Messrs. Wynkoop & Braly are the sub-contractors for steelwork, Mr. R. B. Stone for electric plant, and Messrs. Joseph Edwards & Company for the machinery.

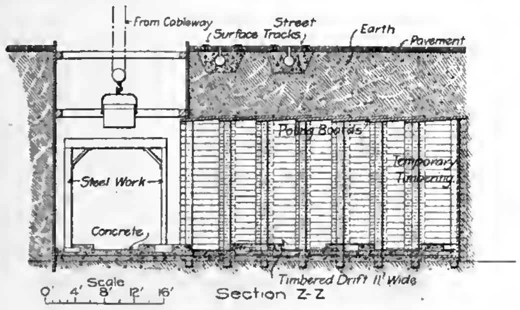
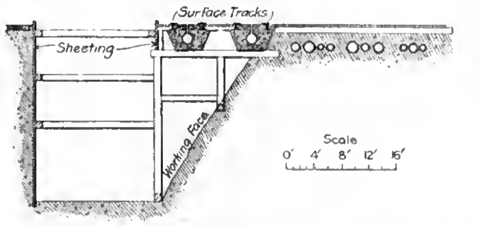
ROLLING HIGHWAY BRIDGE OVER BRONX RIVER, NEW YORK CITY.

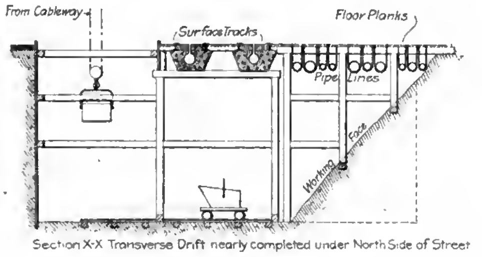
The Second Division of the New York Rapid Transit Railroad.—II.

That portion of Division 2 of the New York Rapid Transit Subway which extends from 41st Street and Park Avenue to 47th Street and Broadway, is about 4,300 feet long and includes the 42nd Street station, near the Grand Central Station. Mr. W. E. Swift is the assistant engineer for the Commissioners, and the work is being executed by the Degnon-McLean Contracting Company, Mr. H. C. Sanford engineer in charge. The structure beyond its connection with the Park Avenue tunnels, is the standard four-track subway except where it is widened at the depot. Above it in the narrow street there are double tracks for electric cars in addition to such a constant and heavy traffic that the excavation was a difficult matter and has been executed largely in tunnel with various systems of headings which make one of the most elaborate and interesting systems of construction on the line.

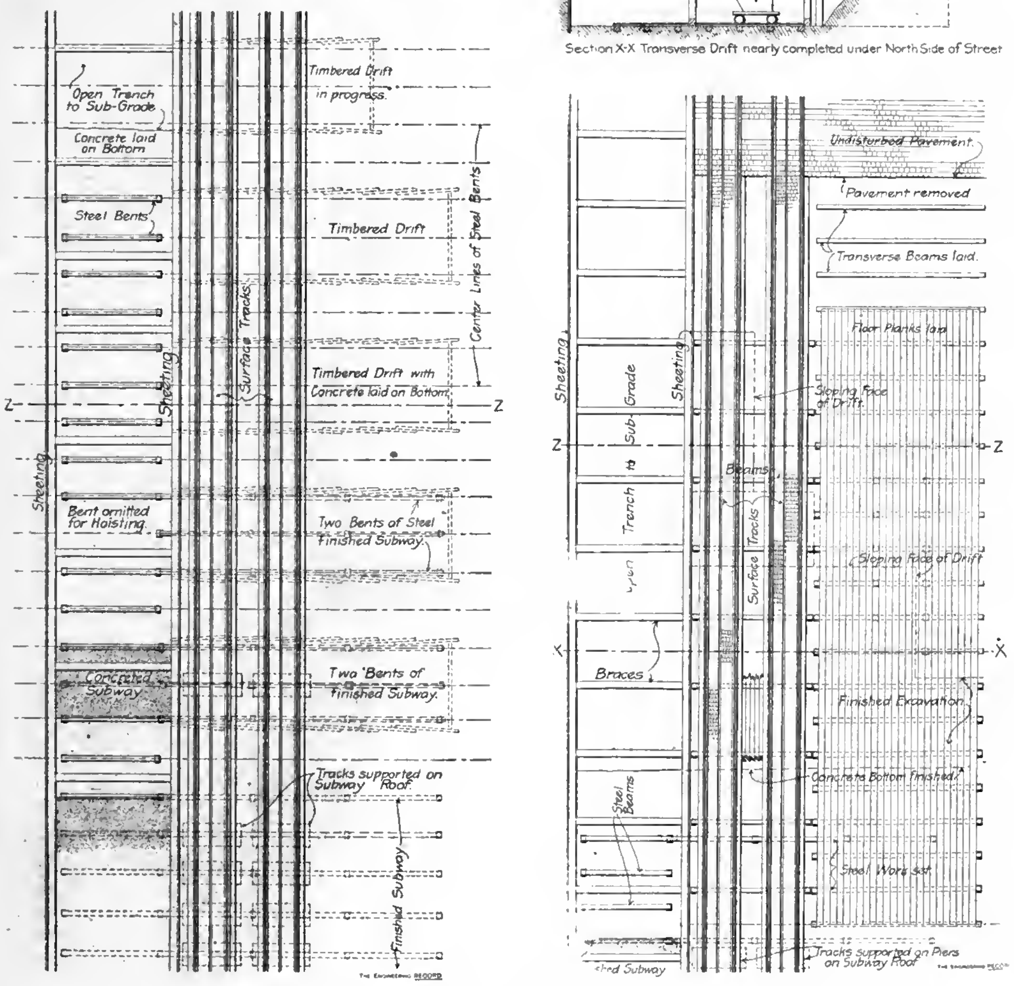




Section Z-Z. Transverse Drift commenced under Surface Tracks.



Section X-X Transverse Drift nearly completed under North Side of Street



SUBWAY EXCAVATION ON FORTY-SECOND STREET; SIXTH AVENUE TO BROADWAY.

The part of the structure in 42nd Street in the middle of the block between Sixth Avenue and Broadway was built almost wholly in earth excavation, which was made with one continuous side trench and alternate transverse short tunnels. A 20-foot open trench was dug to subgrade between the south surface track and the south building line, the sides were braced and sheeted and sidewalk bridges were built over it to give access to the houses. Some of the sidewalk vaults intercepted the line of the subway and were partly removed. The concrete floor was laid the full length of the trench and on it the steelwork for the south track of the subway was erected and the concrete walls and roof completed except in occasional panels where the roof was left open to allow space for hoisting. Spoil buckets and materials were handled by a 300-foot cableway over the center of the trench and by occasional stiff-leg boom-derricks set on the trench timbering and all operated with compressed air from the contractor's plant at 48th Street, near the East River.

Transverse drifts about 12 feet wide and 25 feet apart on centers and high enough to reach from the bottom of the trench to the street surface, were driven from the north side of the trench and extended to the north side of the subway. Each drift was located so as to just receive three bents of the subway steel work, which was erected and the structure completed to its full width in these alternate short lengths. Then similar drifts were run in the spaces between the first set of drifts, giving an opportunity to set the intermediate bents of steel work in them and complete the structure. The surface tracks were supported on brick piers built on the subway roof.

On the ends of the block between Sixth Avenue and Broadway the excavation was 24 feet deep and was generally in earth. It was made with an open longitudinal trench on the south side of the surface tracks, a covered longitudinal trench on the north side of them, and by needling under the tracks and supporting the center of the street intact. A trench 20 feet wide was sheeted down to subgrade between the south surface track and the building line. On the north side of this trench drifts were started under the surface tracks about 10 feet apart, and in them short needlebeams were wedged up against the bottoms of the concrete conduits. A transverse excavation was made the full length of the trench, sloping up at a steep angle from the sub-grade to the needlebeams and as the latter were undermined vertical shores were set under their outer ends. As the transverse excavation continued these shores were successively replaced by longer ones until they finally rested on the bottom of the trench at sub-grade. As the excavation extended farther and farther under the tracks the short needlebeams became disengaged at the north ends and the drifts were advanced beyond the face of the slope and longer needlebeams were inserted, and so on until the needlebeams were carried across to support both tracks and were finally supported by vertical shores from sub-grade at both ends.

Meantime the pavement north of the tracks was removed in short sections, and timbers about 5 feet apart were laid in shallow trenches, and covered with a solid floor of 3-inch planks flush with the pavement. The sloping face of the transverse excavation was worked under this plank platform and the gas and water mains, etc., and the floorbeams above described, were blocked up on needlebeams supported by posts reaching to sub-grade. The floor planks were transverse to the surface tracks and the beams which supported them were longitudinal but are accidentally shown at right angles to their real position in the accompanying plan. The drawings illustrating the excavation methods on Division 2 show the electric conduits under the surface tracks in a conventional manner without attempting to give dimensions or exact form.

In this locality the soil was very loose and soft and was all excavated from sub-grade up to the street level; it was hoisted out of the open south trench by the cableways and derricks and removed in wagons. Movable transverse narrow-gauge tracks were laid on the bottom of the excavation and on them the spoil was transferred in 1-yard steel dump buckets from the foot of the transverse slope to the derrick or trolley hoists. The transverse excavation was made in lengths of 40 to 50 feet and by this method the whole excavation was opened at once and the subway structure was built in full width sections and completed at one operation. After the subway was finished brick piers about 1½ feet wide and 5 feet long were built over alternate roof beams under each track to support the surface street car lines. Where this method of construction was employed the pipes formed almost a complete roof over the excavation near the surface of the ground on the north side of the street; there were fortunately comparatively few on the south side, so that the open trench there and the closed one under the pipes was the most convenient and advantageous way of making the excavations.

Between Fifth and Sixth Avenues the excavation on 42nd Street was from 25 to 39 feet deep and extended from 10 to 27 feet into the rock. A trench 20 feet wide was excavated to sub-grade on the south side of the surface tracks and two 300-foot cableways were installed over its center line to handle spoil and materials. The trench was along the edge of the Bryant Park and the old reservoir site and occupied all the sidewalk, which was entirely given up to it, the pedestrian traffic being transferred wholly to the opposite side of 42nd Street. The bottom of the trench was concreted, the steel work erected and the subway completed for the southern track except that the roof concrete was omitted in occasional panels to provide openings to hoist out the spoil and deliver material through.

A pair of 10x10-inch wooden stringers were laid side by side on the north edge of the completed longitudinal section of the roof, and opposite the middle of them a transverse drift 12 feet wide in the clear and about 20 feet long was excavated with ordinary timbering and poling boards from the north side of the trench to 10 feet beyond the center line of the subway. The roof of the drift was about 3 feet clear above the level of the subway roof, and at a maximum depth of about 15 feet below street level. The bottom of the drift was on the surface of the rock, from 10 to 15 feet above sub-grade. Three 24-inch 100-pound I-beams, 24 feet long, were set transversely with their south ends supported across the pair of 10x10-inch timbers, directly over the subway roof beams and their north ends reaching to the north end of the drifts, one on each side and one in the middle, and were supported by vertical shores as shown in the plan and section of the trench and first drift. The I-beams were wedged up to support the roof timbers and the vertical timbering of the drift was removed.

Excavations were commenced on each side of the drift and carried east and west. Roof poling boards were driven over the top flanges of the 24-inch I-beams, and, when the excavation permitted, another similar I-beam was set parallel to the first one on each side of the drift, a second set of poling boards were driven over it and the excavation continued, and so on as far as the set of I-beams would permit. The north ends of all the I-beams were supported on vertical shores set on the surface of the rock about 8 feet beyond the line of the center columns of the subway. When the upper part of the drift was well advanced, the rock bottom was drilled and blasted out to sub-grade and a second longitudinal section of the subway including the center row of columns, was built in extension of that already made in the trench. The north side of the drift was protected by a bulkhead of braced vertical sheeting boards.

A second 12-foot transverse drift about 13 feet long, similar to the initial one and on its center line was excavated with poling boards from the north side of the first drift to a point 10 feet beyond the third row of columns. Timbers were placed parallel and close to the first three I-beams under the supports of the roof poling boards in the first drift and jacked up on vertical shores until they released the pressure on the I-beams. The latter were then slid north and their north ends supported on vertical shores in the north end of the drift, their south ends being supported across a second pair of 10x10-inch longitudinal timbers set on the subway roof nearly over the middle row of columns. The I-beams were jacked up to support the roof timbers of the drift, the vertical timbers were removed and the excavation continued simultaneously east and west from the sides of the drift as previously.

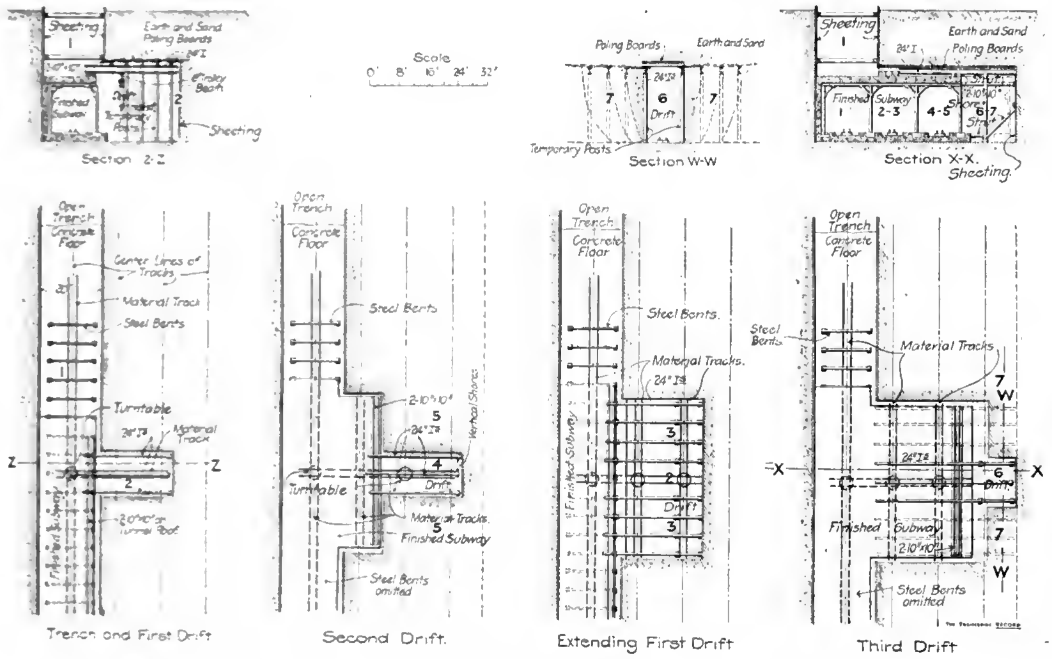
The excavation was completed and the structure for the third subway track up to and including the fourth row of subway columns was built as already described. The excavation required to be extended only about 6 feet farther north beyond the ends of the 24-inch I-beams for the construction of the remainder of the subway, and the same process of extending the initial drift, sliding forward the I-beams in it and then drifting longitudinally from its sides was repeated. It was, however, at first intended to modify this method slightly on account of the short width of the excavation, by allowing the 24-inch I-beams to act as cantilevers and support them only from the last row of vertical posts set for the third track excavation, thus avoiding the use of timbering outside the net limits of the subway. This method is indicated in the diagrams at 6-7 but was finally superseded and the work done as shown at 4-5.

In the plans and sections the successive operations of the excavation are consecutively numbered from 1 to 7. The open trench is 1, 2 is the first transverse drift to beyond the center row of columns, 3 3 are the longitudinal drifts extended east and west from drift 2 and are really carried much farther than is indicated on the diagrams, which are all compressed longitudinally. The second transverse drift, or the extension of drift 2 to just beyond the fourth row of columns is marked 4; 5 5 are the locations in which the second set of longitudinal drifts are to be excavated east and west from 4; 6 is the third transverse drift or the extension of 4 to the north edge of the subway and 7 7 are the third longitudinal drifts proposed to be carried east and west from 6 under the cantilever ends of the I-beams.

The spoil was loaded into 1-yard steel buckets which were suspended from differential hoists carried by trolleys which traveled on the lower flanges of 6-inch I-beams bolted across the lower flanges of the 24-inch beams over the center lines of the subway tracks. These trolleys delivered the buckets to cars on transverse tracks which delivered to the cableway hoists in the open trench, but later the trolleys were replaced by narrow gauge tracks and turntables on the subway floor as shown in the plans and sections.

Near Fifth Avenue, the surface of the rock was so much higher that the height of the earth drift had to be increased to secure working headroom, and the 24-inch I-beams were raised 4 feet. They were carried on a second set of two 10x10-inch longitudinal timbers in the vertical plane of those laid on the north edge of the subway roof, and supported from them by pairs of 10x10-inch vertical posts under each I-beam, both vertical posts and I-beams being securely braced transversely by inclined braces. Rubble masonry walls or continuous transverse piers were built on top of the finished subway roof between the I-beams, and the poling boards were wedged up tight on them before the I-beams were moved. After the subway was completed and the I-beams removed the spaces between these piers and the poling boards were packed full of dry rubble masonry and the poling boards were left permanently enclosed there.

(To be continued.)



Methods of Excavation on Forty-second Street between Fifth and Sixth Avenues.

A Concrete Culvert was built last fall for the Western & Atlantic Railroad near Bartow, Ga., which presents some interesting features, described by Mr. C. B. Wilson in the "Proceedings" of the Engineering Association of the South. The stone box structure which it replaced was being crushed by the weight of the 66 feet of embankment above it, and it was decided to build the new culvert about 30 feet to the north. The latter is 5 feet wide, with full-centered arch; height from bottom of curved invert to springing line of the arch, 5½ feet; thickness of invert and arch crown, 12 inches; and thickness of side walls, 3 feet 1 inch. On account of the great depth, a tunnel 150 feet long was driven from both ends, the open cut being about 38 feet at each end. The headings, from which the earth was removed by wheelbarrows, could only be about 3 feet in length before being timbered up. After the work of laying the invert had begun, the tunnel timbering was found to be settling directly under the track but not at the ends. This was allowed for by increasing the thickness of the invert at the center. After the invert had all been laid, a wooden track was constructed in the upper part of the tunnel, leaving about 4 feet headroom, and a small car from which the concrete for the walls could be easily dumped into the molds was built. For the delivery of sand and cement from the track above, a wire rope was stretched from top to bottom of the slope, and two boxes with drop bottoms were hung from it by small snatch blocks. The 20x30-foot mixing board was built near the lower end of the culvert. The costs of concrete placed, including building of platforms, molds, car, etc., were: In invert $4.76 per cubic yard, in side walls $4.82, and in arch $6.02.

The History of the Institution of Civil Engineers.

Extracts from the Presidential Address of Charles Hawksley.

The early history of the Institution is so well related in the report of the Council for the Session 1885-86, just 50 years after its existence was first announced to the world by the publication of its proceedings, that the following extract from that report may be of interest to at least the younger members of the profession:

"The honor of having originated the Institution is often assigned to Smeaton, or to Telford, but the idea is erroneous in both cases. Smeaton died many years before it was thought of, and Telford only joined it after its establishment. A Society of Engineers, still existing, was founded by Smeaton in 1771; it includes many of the most eminent members of the profession, but it is rather of the nature of a social club than of a scientific association, and has no connection with this Institution. It was, indeed, of too exclusive a nature to meet the wants of so large and mixed a body as soon became engaged in engineering; and early in the present [nineteenth] century a feeling began to be entertained that an Institution on a larger scale, having for its object the furtherance of professional knowledge, might be made eminently useful.

"The persons who took the initiative in the matter were six young men, then beginning their engineering life, William Maudsley, Joshua Field, Henry Robinson Palmer, James Jones, Charles Collinge and James Ashwell. Towards the end of the year 1817, they, impressed with the difficulties of gaining the knowledge necessary for the diversified practice of engineering, resolved to form a society for promoting regular intercourse between persons engaged in the profession, to the end that such persons might mutually benefit by the interchange of individual observation and experience.

"The first formal meeting was held at the Kendal Coffee House, in Fleet Street, on the 2nd January, 1818. The proposal was favorably received; the society was established; other engineers joined, and rules were framed for its government. During two years it continued to meet, and the result of its experience of the value of the meetings was such as to warrant an effort being made to extend the limits of the society. It was perceived that a principal step towards this extension would be to obtain the direct patronage of some eminent and popular professional man. Accordingly, on the 23rd January, 1820, the following resolution was passed:

"'That in order to give effect to the principle of the Institute, and to render its advantages more general both to the members and the country at large, it is expedient to extend its provisions by the election of a President whose extensive practice as a Civil Engineer has gained him the first-rate celebrity; . . . and that a respectful communication be made to Thomas Telford, Esq., Civil Engineer, requesting him to patronize this Institution by taking upon himself the office of President.'

"So little was the society known up to this time, that Telford had never heard of it when the foregoing resolution was announced to him; but appreciating, with characteristic judgment, the value of such an Institution, and the useful results it was capable of yielding, he accepted the proffered chair without hesitation, and was formally installed on the 21st March following.

"Telford's name gave an impulse to the progress of the society, which grew rapidly in importance under his fostering care, until, on the 3d June, 1828, it received a charter of incorporation under the Great Seal, by the title of The Institution of Civil Engineers. Telford died on the 2d September, 1834. A few years before his death he had begun to contract his engagements, and as he gradually withdrew from the toils of business, his attention became more and more concentrated on this society. It was, indeed, the last object of his solicitude, and gave employment to his mind in the evening of his days. Its collections were enriched by his bounty, and when, full of years and of honors, he felt the close of life approaching, he endowed the Institution with the munificent bequest which has since done so much to encourage the production of Original Communications, for reading at the meetings and for publication in the 'Minutes of Proceedings.'"

Thomas Telford was in 1835 succeeded as President by James Walker, another engineer of acknowledged eminence, who occupied the chair until January, 1845.

In 1836 the first volume of the "Transactions" was published; it was in quarto size and contained selected communications, written by men of considerable eminence, together with a short history of early engineering in Great Britain and of the Institution. The publication of the "Minutes of Proceedings," in octavo size, was commenced in 1837, in which year the first published report of the Council appeared. It was then intended to give in the octavo volumes only abstracts of the papers and discussions, certain selected papers being published in full in the quarto form.

In 1842 the third and last volume of the quarto "Transactions" was published, and after the 12th of March, 1844, the papers were published in the octavo "Minutes of Proceedings" in full, or with but slight curtailment. In this form the proceedings have continued to appear, and at the close of the Session 1899-1900 they occupied no less than 142 octavo volumes.

At the end of the year 1844, Mr. James Walker, who had occupied the chair since the death of Telford, a period of ten years, desired that he should not be again nominated, but notwithstanding this he was chosen at the Annual Meeting in January, 1845, and on his declining to serve, Sir John Rennie was elected President.

In 1846 it was enacted that in future no members should be nominated for the office of president more than two years consecutively, and that at the expiration of such two years he should not be eligible for re-election for three years. It was also virtually decided to allow the class of graduates to become extinct, and no elections into it subsequently took place. At the same time it was arranged to admit young engineers as Associates.

The number of the Council was increased in the year 1871 to twenty, and in 1874 there first appeared in the "Minutes of Proceedings," under the title of "Other Selected Papers," certain papers which had not been read at the meetings, and at the same time there were also added "Abstracts of Papers in Foreign Transactions and Periodicals."

An important change in the constitution of the Society was made in December, 1878. Under the Constitution as then amended, the Institution has since consisted of Members, Associate Members, and Honorary Members, all entitled to the privileges of corporate membership, and of Associates (not civil engineers by profession) who are not entitled to those privileges, with the exception of those who were on the Register of the Institution prior to the 2nd December, 1878.

In their report for 1880, the Council alluded to the existence of a general feeling that it would be desirable for a president in future to hold office for one year only. In consequence, the then president, Mr. William Henry Barlow, F.R.S., intimated that he did not wish to be proposed as President a second time. Since that date the former practice of nominating the same person for two years consecutively has not usually been followed, although no change has been made in the By-Laws on the subject.

In the report of the Council presented to the annual general meeting of the Institution in May, 1892, attention was directed to the dearth of professional men in the volunteer regiments of the Royal Engineers, and the hope was expressed that young civil engineers, whose education rendered them peculiarly fitted to fill the vacancies and to be of service to their country, would, in larger numbers than was then the case, prepare themselves by military training to give aid in any national emergency. Recent events add force to the hope then expressed, and the valuable assistance which has been lately afforded by those engineers who volunteered for service in the South African war should be an inducement to young engineers of the present day to go through the training needful to enable them to render efficient aid to the military authorities in defense of their country, should the necessity unhappily arise for calling on them to do so.

The contemplated reconstruction and enlargement of the premises of the Institution having been deferred for several years, in consequence of Parliament having sanctioned the acquirement of the house of the Institution for certain projected street improvements, which were eventually abandoned by their promoters, the Council considered that further delay was, in the interests of the Institution, undesirable, and determined, in the autumn of 1893, to utilize the sites of Nos. 24, 25 and 26 Great George Street, by the erection thereon of the present building from the designs of Mr. Charles Barry. In the month of March, 1896, the temporary premises were vacated, and the offices were opened in the new house, to which the principal portion of the library books was also transferred.

Having now had the use of the new premises for five years, the experience acquired has confirmed the favorable opinion at first formed as to their suitability for the intended purposes; but extensive as they are, it has already been found that one or two additional rooms would be very useful, in view of the increasing number of committee and other meetings held in the building and the augmented office business.

It may be here mentioned that during the year 1895 a new catalogue of the books in the library of the Institution, comprised in three volumes, was issued.

The year 1896 was not only rendered memorable by the completion of the new house of the Institution, but was also notable as having been the year in which important alterations were effected in the charter and by-laws of our Society. The Council were of opinion that the then existing circumstances were such as to render changes in the constitution and the mode of election of the Council desirable in the interests of the Institution; and that view having been concurred in by the members generally, the Council recommended that a supplemental charter should be applied for in order that the desired alterations might be effected. This recommendation was adopted at a special general meeting held on the 6th February, 1896; and on the 20th March, 1896, a new supplemental charter was granted, with reference to which the Council, in their report for the session 1895-96, observed as follows: "Under the new charter the members of the

Institution are at liberty to fix the number of the Council by the by-laws from time to time, thus admitting of the full and proper representation of all engineering interests both at home and in the Colonies and India. The broad principle thus embodied in the constitution has aroused interest and attention in many quarters. The Right Hon. James Bryce, M. P., late President of the Board of Trade, on a recent occasion remarked in this connection: 'It is with the heartiest sympathy that those of us who watch the efforts that are being made in the political sphere to bring the Colonies closer to their mother-country welcome such a step as you are taking, which will unquestionably give you a firmer hold on the members of your profession beyond the seas.' Further, the corporate members are given the power of voting for the election of the Council without the necessity of attending the annual general meetings—a condition which before practically debarred the vast majority of the members from exercising their privileges in the foregoing respect."

On the 15th April, 1896, at a special general meeting, the by-laws were altered so as to bring them into conformity with the powers conferred by the new supplemental charter. The by-laws as then altered provide that "the number of the Council shall be such as the Council in any year may fix for the ensuing year, provided that such number shall not be less than twenty-three or more than thirty-one, inclusive in both cases of the Presidents and Vice-Presidents, but exclusive of such of the Past-Presidents, if any, as may be appointed by the Council," and that "the Council, when elected for the year, may appoint any number of Past-Presidents, not exceeding four, to be members of the Council for the same year." The altered by-laws also prescribed that the balloting list for the council "shall include the names of not less than seven corporate members who have not served on the Council during the current or the preceding year, and the number of names in all shall be at least two in excess of the number of the Council to be elected." Provision was made to enable members to vote for the election of the Council without the necessity of attending personally at the annual general meetings, and the session was fixed to commence annually on the first Tuesday in November and to continue until the end of April, unless it should appear to the Council advisable to protract it. Other minor alterations were also made.

Under the by-laws as so altered, the number of members on the Council has been gradually increased from twenty to the maximum allowed, namely, thirty-one.

On the 9th June, 1896, in consequence of failing health, Mr. James Forrest retired from the post of Secretary, after having been connected with the Institution for no less than 54 years, during which period he had been for 4 years Assistant-Secretary and for 36 years Secretary. In November, 1896, Sir John Wolfe Barry remarked in his inaugural Address as President with reference to Mr. Forrest, that "It may truly be said of him that he has not only watched over the interests of the Institution with the greatest assiduity and with complete success, but that his office has been to him a labor of love. Certainly no man ever devoted himself more thoroughly heart and soul to his work than has Mr. Forrest from first to last during his long tenure of office," an expression of appreciation which I am sure all of you who have had the pleasure of knowing Mr. Forrest or are acquainted with the results of his exertions on behalf of our Institution will agree with me was fully deserved. On his retirement, Mr. Forrest, who to the present day continues to take a keen interest in everything connected with the Institution, was appointed Honorary Secretary in succession to Dr. Pole, F.R.S., who was elected an Honorary Member of the Institution, and whose death during the present year we have had to regret. Dr. J. H. T. Tudsbery (M. Inst. C. E.), who had for four years acted as Assistant-Secretary, succeeded Mr. Forrest as Secretary, and fills the position with an ability and courtesy known to us all.

At a special general meeting held on the 30th March, 1897, further alterations were made in the by-laws, the most important being the introduction of a test, by examination, of the general and scientific knowledge of candidates for election into the class of associate members, with a view to insure that those who are admitted into that class shall, in addition to the qualifications previously demanded, give satisfactory evidence of their acquaintance with those branches of science which form the basis of engineering. Advantage was taken of the revision of the by-laws to define more concisely the several classes attached to the Institution, and to give official recognition to the term "Associate Member," which had been in use since the foundation of that class in 1878.

Membership in the Institution of Civil Engineers.

Date.	Honorary members.	Members.	Associate members.	Associates.	Graduates.	Students.	Totals of all classes.

With the object of promoting union amongst the members of the Institution, and facilitating the interchange of professional views in the case of those whose residence at a distance from London precludes them from regular attendance at the weekly sessional meeting of the Institute, the Council arranged for a general conference of members in May, 1897, at which the large attendance and the interest manifested in its proceedings were so satisfactory as to induce the Council to arrange for similar meetings to be held biennially. The second of the conferences was held in London in June, 1899, and the third was merged in the International Engineering Congress held at Glasgow in September, 1901, in connection with the Glasgow Exhibition.

In April, 1899, the Council nominated Mr. (now Sir) W. H. Preece, then President of the Institution, and Sir John Wolfe Barry, Past-President, to be the first representatives of the Institution on the General Board of the National Physical Laboratory, which has now acquired a home at Bushy, near Kew, where it is confidently anticipated that scientific researches of considerable practical value to civil engineers will be conducted.

The Council, in their report for the Session 1899-1900, call attention to the condition under which admission to the Institution as a corporate member is granted, viz., that the applicant shall be "regularly educated as a civil engineer" in some branch of the profession, and they set out the regulations which they had framed with the object of indicating more definitely the regular education contemplated by the by-laws apart from the examination or other tests in force. It cannot, in my opinion, be too strongly insisted on that these examinations and tests are only to be regarded as supplementing, and not in any sense as superseding, that practical training in actual work which is essential to the education of a civil engineer.

The progress of the Institution, as indicated by the number of members and others associated with it at various dates in the Nineteenth Century, is shown in the accompanying table, and it is worthy of note that in 1860, 42 years after the Institution was established, the total number of all classes on its books was only 930, yet 40 years later, namely, in 1900, the total number had become no less than 7,359, being an increase in that period of 6,429, thus making the total number in 1900 nearly eight times as great as in 1860.

It may not be out of place to put on record that the accounts for the financial year ended the 31st March, 1900, show that the income of the Institution during that year amounted to £22,735 1s. 8d., in addition to which £2,470 13s. was received on capital account and £470 8s. 11d. from trust funds, making a total of £25,676 3s. 7d. The expenditure during the same period was on income account £21,465 17s. 2d. and on account of trust funds £517 5s. 7d. At the end of the financial year the Institution held investments in railway and other securities valued at nearly £55,000, in addition to the freehold premises in Great George Street with their contents. The financial position of the Institution at the close of the nineteenth century may therefore be regarded as highly satisfactory.

A Test of the Safe Load for Piles was made a few years ago at New Quay, Royal Victoria Dock, London, which has been described in "Engineering." The piles driven in some of the work at that place when 36 to 38 feet in the ground were found to respond to the blows of the hammer more than had been expected. A test was accordingly made of one which had been going at the rate of 2¼ inches to four 8-foot blows of an 1,800-pound monkey. The pile was of pitch pine 36 feet in length below the cut-off and 12½x11½ inches in cross section. The head of the pile was loaded with steel joists weighing 56.8 pounds per foot. A small indicator was arranged just above the level of the ground to record the deflection, which was as follows:

At 10 tons.	No deflection.	Remained thus	24 hours.
" 20 "	1/16 in.	"	48 "
" 30 "	1/16 in.	"	0 "
" 37.5 "	3/16 in.	"	7 days.
" 56.9 "	1/4 in.	"	4 weeks.

At the end of this time there was no further deflection. On the load being removed the pile rose 3/16 inch, showing that a great deal of the deflection was due to the fibers of the timber being put in compression.

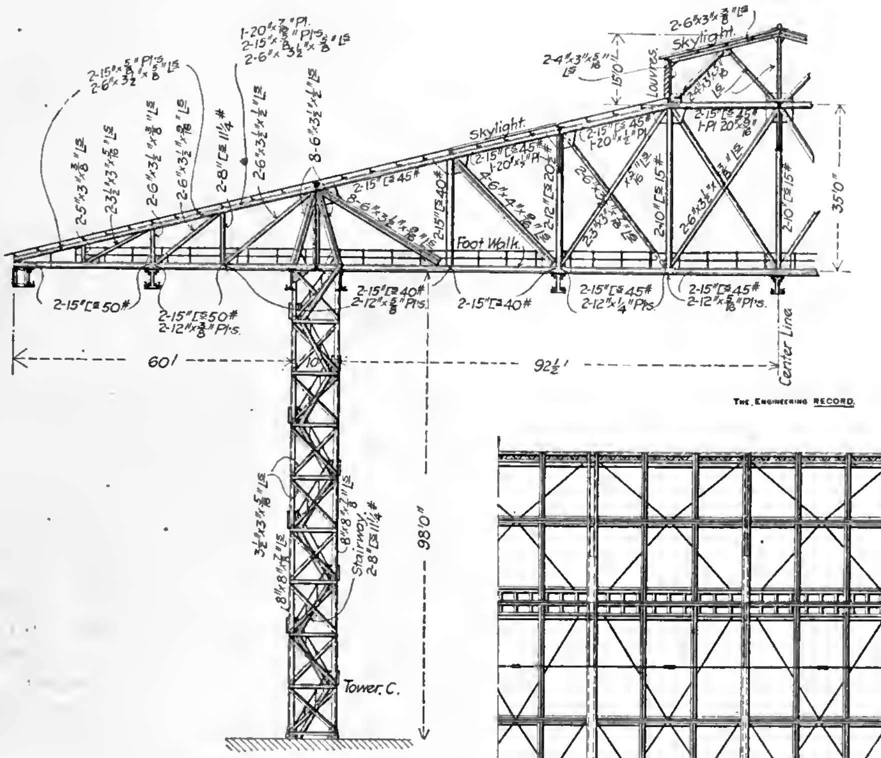
Liquid Fuel Burning Without the Steam Jet is accomplished by Mr. R. A. Meyer, superintendent engineer of a Dutch steamboat line sailing between Batavia and Singapore, in the following manner. The oil is forced into the furnace by means of a donkey pump, the oil coming from a storage tank through a small heater in which it is warmed slightly by the exhaust from the pump, the exhaust after passing from the heater going to the ship's condenser, as the apparatus is designed to save the fresh water which would have to be supplied if the steam jet were used. The oil is discharged by the pump through another heater, through which live steam for the donkey pump is passed, and is heated to 200 degrees Fahrenheit. The front end of the furnace is closed with a cap of steel, and an annular space is formed around this into the furnace, with spiral air guides to cause the inflowing air to take up heat before entering the interior where the coil is burning. Part of the air is allowed to ignite with the oil as it sprays from the injector, but the bulk of combustion is completed further on. No air blast is used, the design being simply to heat the air by the radiation from the oil flame.

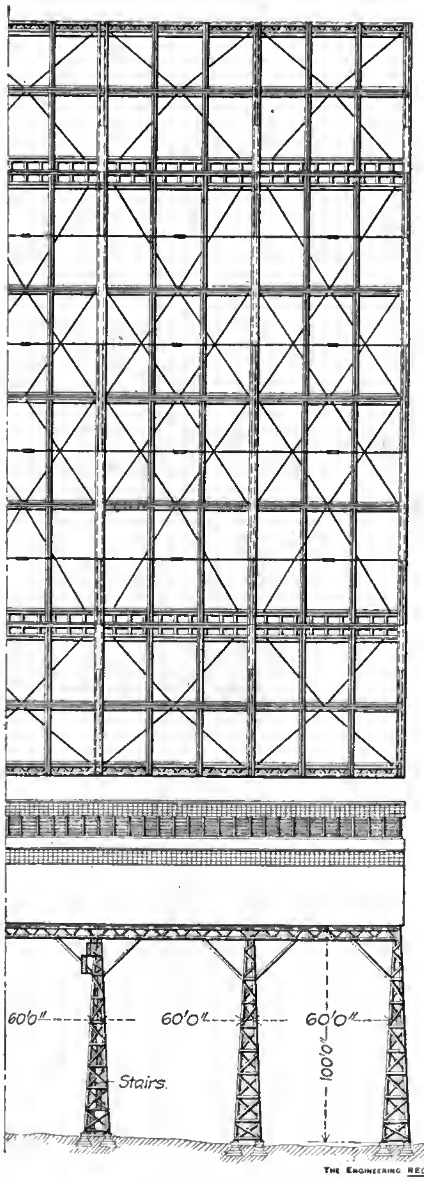
The Fore River Ship Building Shed.

A large steel shed of a special type has been recently designed for the ship building berths of the Fore River Ship & Engine Company, at Quincy, Mass. It will shelter four large ships under simultaneous construction and afford all desirable facilities for handling and transporting the structural materials and machinery and for assembling the frameworks. Multiple systems of independent overhead girder cranes are provided, which command the whole area of that portion of the shipyard which is under cover and handle all materials and tools quickly without having the service for any one of the four vessels obstructed by that for the other three and without any fixed or movable tracks or apparatus on the ground and only two longitudinal rows of vertical members to carry the building and the crane service. This system obviates the use of gantries, derricks and fixed crane service, reduces the obstructions in the yard, economizes spaces, provides shelter for the vessels under construction and, being equipped with specially quick-acting separate electric motors for hoisting and traversing the different cranes, provides means for rapid work.

The shed is 480 feet long and 325 feet wide, and has a roof which is over 150 feet high to the top of the lantern and 100 feet clear above the ground. There are nine main roof trusses, 35 feet deep in the center, which are supported on two longitudinal rows of towers 195 feet apart on centers. The roof trusses overhang the towers 60 feet in the clear on each side, and are intended to have ways under them which will accommodate two large battle ships in the center span and a large merchant ship under each cantilever.

The towers are 10 feet square at the base, with four columns in each. The columns are battered about 4:100 in vertical longitudinal planes, so that the tower is wedge-shaped with a longitudinal length of about 2 feet at the top and a uniform transverse width of 10 feet from top to bottom. Each column is made with a single 8x8-inch angle with the flanges turned in and is seated on a separate offset masonry pier with its cap stone just above the surface of the ground. There are horizontal angles riveted across all faces of the tower dividing it into vertical panels about 11 feet high, which are X-braced with single angles riveted across opposite sides of the column flanges in the same panel, so that their outstanding flanges will clear at intersections. The width of the column angles allows the bracing angles to be riveted directly to their flanges and dispenses with connection plates. Gusset plates and horizontal connection angles are riveted to the ends of the columns for the cap and base plates, and in two of the towers in each row there are zigzag inside stairs giving access to the girder cranes at the level of their tops. At the shore end of the shed the towers are 100 feet high, with their bases carried down below high-water line, but as the ground slopes up away from the shore and the roof line is level, the heights of the towers decrease to 87 feet at the opposite end, where the foundations are at a correspondingly higher level.





Steelwork of Ship Berth Sheds.

Longitudinal cap plates unite the tops of the pairs of tower columns and receive the bearings of the lower chords of the roof trusses, which are continuous over the tops of the towers. The reactions from the trusses are transmitted to the towers through a pair of very heavy inclined braces intersecting at the top chord and seated on the bottom chord over the tops of the columns. The top and bottom chords of the trusses have rectangular cross-sections made up of 12-inch cover plates and pairs of 15-inch side channels, with gusset plate connections for the vertical and inclined web members. The vertical members are made with pairs of channels, latticed, and the inclined ones with angles, of which there are eight in the heaviest ones and two in the lightest ones in the center and end panels.

The trusses are connected by five lines of longitudinal lattice girders with their flanges flush with the top chords of the trusses and web connected to the vertical members of the trusses. One line over the center of each row of towers is 17¾ feet deep, the line in the centers of the trusses and the two intermediate lines are 10 feet deep, with six panels each. The tower lines are as deep as the trusses at those points, and are connected to both top and bottom chords and to the tower caps. At points one-third of their lengths from the towers they are braced by 45-degree struts about 27 feet long, reaching from the lower flanges in vertical planes to the sides of the towers at the second panel point from the top.

The longitudinal girders support jack rafters 20 feet apart, which carry horizontal purlin angles about 6 feet apart. In the main span of the roof trusses there are four lines of ¾-inch adjustable longitudinal rods continuous from end to end of the building, and every panel of the roof is X-braced by rods in the plane of the rafters, as shown in the general plan. The roof trusses which are supported on the stairway towers carry footwalks and railings on their lower chords to give access to the different girder cranes.

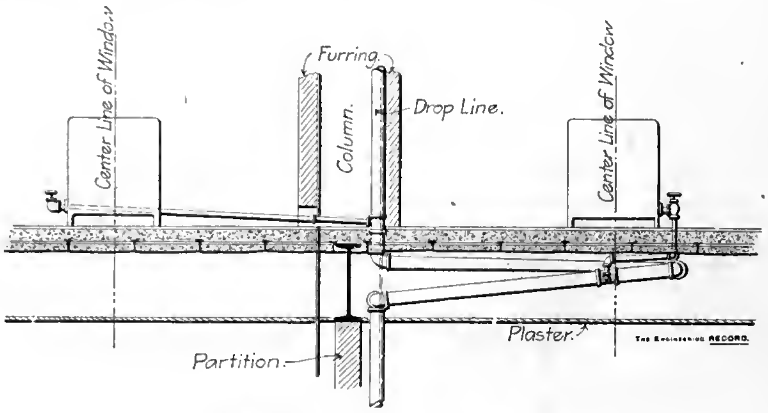
The lower chords of the roof trusses are connected by eleven lines of longitudinal crane girders suspended from them, and by two lines of light fascia girders at the eaves. The center three lines and the lines in the centers of the cantilever ends of the trusses have double webs, the other lines, one on each face of each tower and one near the end of each cantilever, have single webs and all of them have T-rails for the crane tracks set on the upper side of their lower flange angles. This arrangement provides separate parallel tracks for eight sets of independent girder cranes, two sets of one or more cranes over each ship. All are of 5 tons nominal capacity and are from 25 to 45 feet spans.

The roof is covered with No. 18 galvanized corrugated iron, and has a skylight 20 feet wide reaching from end to end on each side of the lantern. The lantern is 45 feet wide and 15 feet high and has iron ventilating louvres on the sides and skylights in the roof. The roof trusses are proportioned for dead load and 40 pounds uniform distributed load per square foot of roof surface and for the crane loads and for an assumed wind pressure of 20 pounds per square foot of roof surface. Medium steel is used throughout and is proportioned for unit strains of 18,000 pounds bearing, 10,000 pounds shear, 15,000 pounds tension and 12,500 pounds properly reduced for compression. Unit strains in field rivets and bolts are 15 per cent. less than for shop rivets and bolts.

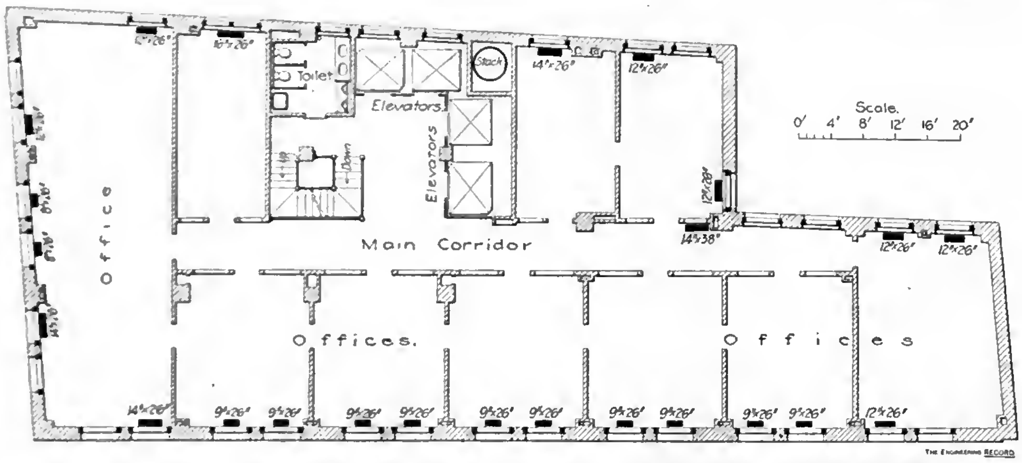
The shed and cranes and a special 75-ton folding jib gantry crane were designed, built and installed by the Wellman-Seaver-Morgan Engineering Company, Cleveland.

The Mechanical Plant of a New York Office Building.

In a new 15-story office building at the corner of Cedar and William Streets, New York, there has been installed a mechanical plant which is of interest in many respects. One of the features of the installation is the use of two internally fired Scotch marine boilers, which were adopted in this instance on account of lack of room in the basement and because they could be covered and insulated in such a manner as to prevent in the greatest degree any heat being felt on the main floor above the boiler room. Another interesting feature in connection with the plant is that steam is circulated throughout the heating system at atmospheric pressure without special devices. Two electric light units furnish current to 1,800 incandescent lamps throughout the structure, four hydraulic elevators have been installed, and there is a one-pipe heating layout fed from overhead mains. Special provision has been made in the building against fire and the floors are of concrete construction. Most of the piping has been concealed, and that which is exposed is arranged so as not to be unsightly. The good appearance of the engine room is enhanced by covering the walls with white tile.



Method of Making Connections with Radiators.



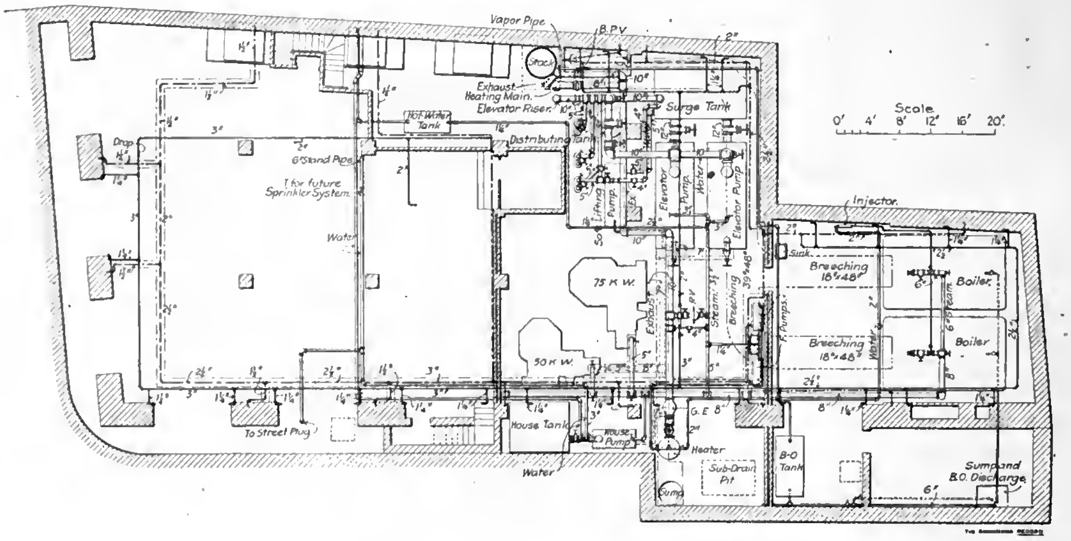
Typical Floor Plan, showing Direct Radiation.

The building is of steel skeleton construction and covers a rectangular area of about 4,800 square feet, the main entrance being on William Street, where there is a 60-foot front. The total depth of the structure is 124 feet. A typical floor plan is given in one of the accompanying illustrations. The boiler plant occupies a portion of the basement on the Cedar Street side, while to the front of it is the engine room. Two elevator pumps are located in the engine room on the left, connected to a surge tank, while a house tank with its pump, a feed-water heater, etc., are on the right. The electric light units are centrally located.

The boilers which are before mentioned are of the internally fired Scotch type, two in number, each being of 200-horse-power capacity, rest individually on saddles and very little setting has been necessary. They are about 15 feet in length and 9 feet 6 inches in diamater, fitted with Morison corrugated furnaces each delivering steam from 6-inch outlets on the top of the boilers to an 8-inch header extending along one side of the engine room. It is suspended from the ceiling and is run to a point near the house tank where it drops below the flooring and is fitted with a blind outlet so as to form a water leg. A 2-inch drip is carried from the bottom of the latter to an Anderson trap. The main exhausts from the engines are shown leading to a Ford grease extractor and into the heating main.

The engines are of the Harrisburg single expansion, horizontal high speed type, one is a 14x12-inch engine and the other a 10x12-inch, the former being direct-connected to a 75 kilowatt Westinghouse multipolar compound wound 120-volt generator and the latter to a 50-kilowatt machine of the same type and manufacture. A 4-inch steam line from the main header serves the smaller one and a 5-inch line supplies the larger engine. The main exhaust line from engines and pumps is 10 inches in diameter and is run from the grease extractor mentioned to a point near the smokestack where it rises to the attic, serving downward heating lines. To the rear of the engines are two 6x4x6-inch boiler feed pumps made by the Buffalo Steam Pump Works, fitted with brass lined cylinders, which pump the water of condensation from the heating system back through a 200-horse-power Berryman feed-water heater into the boiler. A 10x6x8-inch house pump, also made by the Buffalo Steam Pump Works, is supplied with steam through a 2-inch connection and exhausts through a 2½-inch line; it draws from a house tank 6½ feet by 8 feet in plan and 6 feet deep, divided into two sections, one for flushing the toilets and the other for drinking purposes. Water connections to and from this tank are shown, the latter running across to the opposite side of the building where it rises to a roof tank in a pent house. The roof tank is capable of holding about 2,000 gallons, and the water level is automatically regulated by a ball float operating in connection with the admission valve on the supply pipe.

Other apparatus belonging to the steam plant proper is a blow-off tank 8 feet long and 3½ feet in diameter, the boiler connections for which are shown. Also a hot-water tank, 3 feet in diameter by 6 feet in length, which is suspended from the ceiling by means of wrought iron straps and hangers. The temperature of the water in this tank is kept at a desirable point by a Davis & Roesch thermostat. All steam piping, tanks, etc., have been covered with magnesia insulation made by the H. W. Johns-Manville Company of New York.



Plan of Mechanical Plant in Basement.

The electrical equipment includes the two 120-volt multipolar generators mentioned which supply current to a two and three-wire lighting current supplying incandescent lamps in various parts of the building. There are four general centers of distribution as follows: One circuit to the second floor supplies the first, second and third floors; a line to the fifth floor furnishes current to the fourth, fifth, sixth and seventh stories; another to the ninth takes care of the eighth, ninth, tenth and eleventh; while the last, running to the thirteenth floor, connects the twelfth, thirteenth, fourteenth and fifteenth. A panel box is provided for each floor, from which taps are taken to outlets. In several places flexible conduits are used, generator feeders being run under the engine-room floor to the switchboard in loricated conduits.

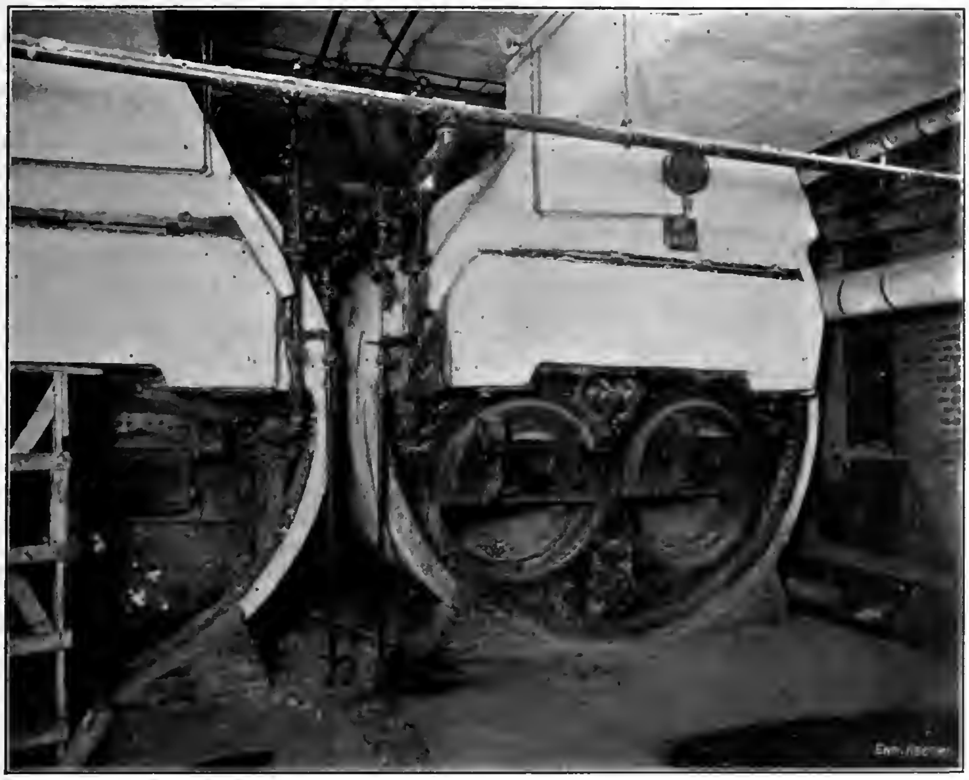
The switchboard consists of two panels of white Italian marble and is located at one corner of the engine room. On it are placed two ammeters and two voltmeters of the Weston type, a ground detector, two pilot lamps for the generators and two Carpenter rheostats. There are also contained on the board two large generator switches, a break-down switch and switches for the control of the four centers of electrical distribution mentioned.

The elevator equipment was installed by the Otis Elevator Company, of New York, and includes four hydraulic elevators and a safe lift. The two compound tandem pumps are of the Worthington type and are duplicate machines, each being 14x20x11x15 inches in size. Either or both may be used for obtaining the necessary pressure in the elevator tank, 4 feet in diameter and 16 feet long, which is set on steel girders. A surge tank to which the pumps are connected in the usual way is 7½ feet by 12 feet in plan and 6 feet in height, holding about 15,000 gallons. The customary automatic cut-off valve operating when the cars have reached the end of their transit is provided and Cruikshank safety devices are installed on the cars. The safe lift pump, connected to the surge tank and also of the Worthington type, is 10x4½x10 inches. Each elevator has a carrying capacity of about two tons and a speed of approximately 500 feet per minute, traversing a vertical distance of 200 feet.

Exhaust steam is used for the heating system, which is of the one-pipe overhead type, direct radiation being installed throughout. The 10-inch heating line already mentioned serves individual attic mains which in turn supply thirteen different drop lines. The radiators are those manufactured by the United States Radiator Company connections for which have been made according to the detail sketch, and expansion joints have been provided at an intermediate floor. Live steam passed through an 8-inch Ford reducing valve located at the junction of the exhaust heating main in the basement and a branch steam line from the main header may be used in addition to the usual heating supply should severe weather warrant such. In connection with the drop lines ½-inch air lines are run, which extend from the top of the building to the basement, there connecting with a small air pump.

The engine room is ventilated by means of a 36-inch Seymour disc fan located in one of the walls and driven by a small motor. No ventilation except through window openings is provided on the floors above. A pneumatic tube system is also installed.

The building was erected from the plans of Mr. Goldwin Starrett, of the Thompson, Starrett Company, of New York, and the mechanical plant was designed by Mr. McGonagal of the same company, who were also the contractors for the installation.



The Scotch Marine-Type Boilers.

An English Municipal Ice and Cold Storage Plant.

The corporation of Wolverhamptom, England, has now in operation a cold storage and ice plant which forms part of a scheme comprising a wholesale market. The latter is now being designed and the total estimated cost, exclusive of site, is about $115,000. At a recent meeting of the Incorporated Association of Municipal and County Engineers, the plant was described by Mr. George Green, borough engineer of Wolverhampton.

The cold stores at the present time comprise five cold storage rooms, having a capacity of 16,650 cubic feet. One of these rooms is intended to be kept at a temperature of about 35 degrees Fahr.; the other four at 22 degrees. In addition to this there is an ice cellar with a cubic capacity of 3,750 feet. The motive power for working the air-cooling apparatus and for manufacturing the ice is electricity, supplied from the corporation mains at about 2 cents per kilowatt hour. The ice machinery has a capacity of 10 tons of can ice per day of 24 hours and the cellar will store 90 tons.

The plant has been supplied by the Linde British Refrigeration Company, and consists of two compressors; one surface evaporating ammonia condenser; one ice tank, complete with necessary moulds; one filling tank; one thawing-off tank; one overhead electric travelling crane; and one air-cooler, with fan, and the necessary motors. The compressors are horizontal, double-acting and belt-driven, the larger one being generally used for ice making and the other for the cold stores.

The air-cooler consists of a series of coils of special lap-welded wrought-iron tube. The evaporation of the ammonia in the coils is utilized for cooling the air, the surface of the coils being kept free from snow by means of a drip of uncongealable brine, the brine being circulated by a brass-fitted pump, worked by a separate motor. The fan, provided for circulating the air over the coils, is placed in a duct, and the air is drawn in by the fan at one end and passed out at the other end, after being cooled, shutters being fixed in each store at convenient places to let in the cold air in such quantities as may be required from time to time.

The ice tank contains 140 moulds or cans of turned steel, in frames, each block of ice weighing 140 pounds, and measuring 42x20x6 inches. The tank is fitted with a propeller for circulating the cold brine over the coils and round the ice moulds. The ice is made from the ordinary water supplied from the corporation mains. Hydraulic agitating gear is also provided for rendering the ice clear to within something like 7 per cent. of the total capacity of the block.

The insulation of floors, walls and ceilings cost approximately 24 cents per cube foot of storage. The floors of the stores were, in the first instance, constructed of 6 inches of cement concrete, upon which, in the case of the ice cellar, was laid ¾ inch of rock asphalt; this was continued up to the damp-course and joined to that by means of a hot seam.

The ordinary method of floor insulation was deviated from in this case, and consists of three slabs, laid one above the other, of a patent material, consisting of granulated cork cemented together and forming a solid slab or brick. Upon the top of these were placed two layers of rock asphalt 1¼ inches thick. This floor has been found an excellent insulator, and at the same time has the advantage of being solid. The author considers it an improvement on the wooden floor, inasmuch as it can be thoroughly cleansed, and should any liquids be spilt upon it no damage can be done to the insulation.

The walls and the ceilings are insulated with timber and slag wool. In the first instance, 2x2-inch red deal studs, 18 inches center to center, are secured to the brick walls with plugs. They are afterwards covered and the spaces between them, with one layer of Giant insulating paper, secured to the studs with tacks and marine glue. Immediately upon this are placed two layers of 1-inch red deal grooved and tongued boarding, the first laid horizontally and the second vertically, with one layer of similar waterproof paper between; 2x9-inch red deal uprights at 18-inch centers are then fixed, to which are attached again two layers of 1-inch grooved and tongued boarding, with waterproof paper between, as previously described. The 9-inch space is carefully and firmly filled with slag wool. The ceiling is treated in a similar manner, slag wool, of course, being put in from the top before the upper boarding is laid.

In the case of the ice cellar, the walls are covered with asphalt up to the top, and after the insulation has been fixed in a similar manner to that in the stores the inside walls are then fitted with 2x1-inch dunnage or cargo battens at 15-inch centers, to prevent the blocks of ice adhering to the walls, and to admit of a free circulation of air around the materials stored. The ceiling of the ice cellar is largely formed by the bottom of the ice tank, and has no means of being kept cool otherwise than by the tank.

Each doorway also has a canvas Willesden curtain to prevent unnecessary escape of cold air. The whole of the inside of the stores is painted in white and finished in white enamel, so as to make the same as light, clean and sanitary as possible. The entire building is lighted by electric light.

New Books.

Although only six years have elapsed since the publication of the first edition of Prof. William P. Mason's "Water Supply," so much material has since been added to the stock of general knowledge on the subject that no inconsiderable portion of the text had to be rewritten for the third edition, which has just appeared. As the work now stands it is a digest of all the important information the author could collect on the subject, considered from a sanitary standpoint. The relations between drinking water and disease, water purification, the quality of supplies from various sources, the effect of storage, the pollution of supplies, and the action of water on metals are the general features of the book, which is profusely illustrated. It is published at $4 by John Wiley & Sons, New York.

The Association of Civil Engineers of Cornell University publishes every year a volume of "Transactions" which includes addresses by non-resident lecturers and other papers of permanent value. The volume for 1901-2 is a book of 136 pages and contains nine good articles. The introductory paper is on "Bridge and Concrete-Steel Construction" and was written by Mr. Edwin Thacher. It is mainly a compilation of experimental data useful to designers of concrete-steel structures and a statement of a theory of the ultimate strength of such construction which Mr. Thacher has found to agree well with tests. The other papers are as follows: "Railway Management and the Civil Engineer," by Mr. Theodore Voorhees; "Heavy Sewer Construction in Concrete," by Mr. E. J. McCaustland; "Hook Mountain Tunnel," by Mr. Wager Fisher; "New York, Chicago & St. Louis R. R. Bridges," by Mr. A. J. Himes; "Problems and Methods of the Isthmian Canal Surveys," by Mr. Boyd Ehle; "Notes on New Orleans Drainage," by I. W. McConnell; "The Engineer in Construction Contracts," by Mr. John C. Wait; "Anti-Friction Bearings," by Mr. Henry R. Lordly. The book is sold at $1 by the Secretary, Prof. C. L. Crandall.

The Committee on Sewerage of the Connecticut Society of Civil Engineers have presented a report giving some valuable data in regard to the methods of sewer construction and maintenance in some 80 odd cities and towns, chiefly in Connecticut and Massachusetts. This report is published in the "Proceedings" of the society, recently issued.

A volume entitled "Alternating Current Machines," by Prof. Samuel Sheldon and Mr. Hobart Mason, though primarily intended as a text-book is such an excellent treatise on the subject of alternating currents that engineers generally will find it helpful in solving many of the problems that arise from time to time in alternating current practice. Of the many attractive features of this book probably the most notable is the attention given to the physical side of the science, so that the student may get a conception of what actually happens in a circuit, and which, if clearly understood, gives a far better grasp of the subject than do the mathematical and graphical sides. An experiment for demonstrating the lap of multiphase current waves is one of several described in the book which are new, and as an example of original treatment the chapter on converters may be taken. It should also be mentioned that the complete derivation of the formula for line inductance is here given and in its simplest form. The book is no proper treatise for the lazy mind. The rapidity with which a subject is caught up, gone into, the meat extracted and then dropped for another requires close attention and an active mind on the part of the reader. The book is published at $2.50 by the D. Van Nostrand Company, New York.

A small book that is full of good and clearly expressed information is Mr. A. A. Atkinson's "Electrical and Magnetic Calculations." In fact there is so much in this little work that it might well have been given a more ambitious title. It covers continuous and alternating currents, wiring and transmission lines, batteries, magnetism and electro-magnets and dynamo design and calculations, including both continuous and alternating machines. Two plates are inserted from which drop, size, current, and other characteristics of distribution systems may be graphically determined. In order that the reader may clearly understand every formula and its use, numerous examples are interspersed throughout the book and they help to make easy the interpretation of the mathematics. It is particularly valuable as a reference book. It is published at $1.50 by the D. Van Nostrand Company, New York.

An elementary book by Alton D. Adams bearing the comprehensive title "Light, Heat and Power in Buildings" has been published at $1 by William T. Comstock, 23 Warren Street, New York. It may prove of interest to those unfamiliar with the generalities of the theory, costs and operation of power plants for buildings, and its arrangement of the discussion of the various points of such plants will be found convenient. The last chapter of the work includes a discussion of the heating power of fuels, together with a compilation of tests and analyses of various classes of fuel.

In these days of many books, with more of them being ground out every day, it is a pleasure to get hold of a work such as the "Electrical Catechism" issued at $2 by the Hill Publishing Company, New York. Electrical works in the question-and-answer form and alleged to contain instruction in the elementary principles of the art there are in plenty, but they are generally wandering, tiresome and compiled from electrical catalogues by persons who know but little more than the pupils they propose to instruct. The book under review, however, is a departure from the usual type. It is a smart, clean cut work in which the information is correct, well explained and up to date. In short it is good enough for an engineer's library and simple enough for the beginner. The subjects treated are such as logically find their place in such a book, the general theories of electricity and magnetism, distribution, control and design.

The steady increase in the percentage of the total population of the country which dwells in cities and towns makes the study of municipal affairs an obligation of growing importance to all citizens. There is a small number who understand the magnitude of these problems and are endeavoring to solve them, but the mental attitude of the majority of that body of citizens proud to call itself the intelligent class is simply one of befogged conceit. They are the first to assert the intricacy and detail of their own particular calling and the time it takes to master it, yet few of them will fail to give, on the slightest provocation, an opinion on the management of public affairs marked by such a lack of knowledge of legal restrictions, historical precedent and technical information that the decently informed hearer is at a loss whether to laugh or swear. The Macmillan Company, New York, has recognized this condition and has published at $1.25 each a series of books on different subjects of interest to citizens desirous of fulfilling their obligations to the city, State and nation. The last of the series is "Municipal Engineering and Sanitation," by M. N. Baker. The author has had exceptional opportunities for acquiring definite information on the subjects covered by the title of the volume, which he has set forth with the accurate sense of proportion that only comes from a long practical association with municipal affairs. The contents of the book are divided into five parts, ways and means of communication; municipal supplies; collection and disposal of wastes; protection of life, health and property; administration, finance and public policy. No claim is made to review any of these branches exhaustively, as the book is intended for people without technical training who are striving as officials or citizens to improve municipal conditions. It can be heartily recommended for this purpose and deserves a wide circulation and careful study.

A book of vest-pocket size by Mr. H. B. Andrews entitled "Handbook for Street Railway Engineers," contains much useful information concerning mensuration, laying out of curves, track construction, earthwork, copper calculations and the usual trigonometrical tables. While there is little new either in the matter or its treatment, the book forms a handy reference for general use and is based on such excellent models as are found in the Boston street railways. It is published at $1.25 by John Wiley & Sons, New York.

The So-Called Flint Pavements of Lafayette, Ind., which are now attracting considerable attention in that State, are made from a silicious limestone which is found on the Wabash River about 14 miles southwest of the city. Mr. G. H. Stevenson, city engineer, states that the exposed layers of the ledge have the appearance of compact stone, but a light blow with a hammer will break it into small pieces. This ledge, after exposure to the air, can be loosened with an ordinary plow and is very easily handled; the loosened stones range in size from 3 inches down to less than ½ inch. This stone has been used on the streets of Lafayette for a great many years. Formerly it was spread on the street the same as pit gravel and left for the traffic to compact, which took some time, as this stone has very little cementing qualities of its own. Of late years the city has used an 18-ton steam roller in making flint streets. The stone is put on in 3-inch layers and rolled dry until there is no creeping of the pieces under the roller. Then about an inch of clean coarse sand is spread over the layer and washed into the interstices with water from a sprinkling wagon, care being taken not to drench the roadway; the amount of water used is left to judgment of the inspector or engineer. After sprinkling the layer is again thoroughly rolled before the next layer is put on. This operation is repeated with each layer, the total depth of stone used depending on the traffic of the street, and varying from 6 to 12 inches on different streets. Lafayette is partly underlaid with gravel and sand and partly with clay. When flint is used on a street where there is gravel subsoil no special foundation is made beyond shaping and rolling the subgrade, but where the subsoil is clay either an 8-inch telford foundation or a rough stone foundation is made. Where these foundations are used the depth of flint is 3 inches at the sides and 6 inches at the center. This stone makes a very hard and clean roadway, free from dust, which is uninjured by hand sweeping.

Personal Notes.

Mr. R. M. Phelps has been re-elected city engineer of Berkley, Va.

Mr. E. Lacey Chinn has been elected engineer and surveyor of Annapolis, Md.

Capt. A. H. West, of Rosedale, Miss., has been elected chief engineer of the Mississippi River levee commission and Mr. Robert Somerville, of Greenville, Miss., chief assistant engineer.

Mr. Charles H. Ewing has resigned his position as chief engineer of the Central New England Railway to accept a position as division engineer on the Philadelphia & Reading Railroad, with headquarters at Reading, Pa.

Mr. H. C. Brubaker, Jr., has withdrawn from the firm of Samuel H. Brubaker & Co., and has opened offices for engineering and architectural work in the Aetna Building, Indianapolis, in association with Mr. W. K. Eldridge, lately with the same firm.

Mr. W. S. Jones has been appointed general manager and assistant to the president of the Arkansas & Choctaw Railway and the Choctaw Construction Co., with headquarters at Hugo, I. T. He was recently general superintendent of the Rutland Railway in Vermont.

Mr. H. A. Sumner, M. Am. Soc. C. E., has resigned his position as chief engineer of the New Mexico Railway & Coal Co., owners of lines embraced in the El Paso-Rock Island Route, to accept a similar position with the Denver, Northwestern & Pacific Railroad Co., which has been incorporated to build a road between Denver and San Francisco by way of Salt Lake City.

A 30-inch Riveted Steel Force Main, laid last summer to supplement the water supply of Atlantic City, N. J., is described in the 1901 report of Superintendent W. C. Hawley. The method of coating the pipe is of special interest on account of the corrosive action of the meadow mud in which part of it was to be laid. Each length was made up of five alternate inside and outside rings of ¼-inch open-hearth steel, the diameter of the inside rings being 30 inches and the total length of the section being 28 feet center to center of rivet holes. After riveting and calking the seams inside and out the pipe was heated by a jet of natural gas burned inside to a temperature of about 400 degrees Fahrenheit and then coated by dipping it into a bath of mineral rubber heated to the same temperature. The pipe was lifted out of the bath slowly so that the surplus coating material would run off, and it was then placed on end inside a frame scaffold and two strips of 10-ounce burlap wide enough to encircle the pipe and lap a few inches were applied immediately by a gang of paper hangers and brushed into the hot coating. In laying the pipe across the meadows branches were inserted at six points to connect to the two old mains, allowance being made for expansion and contraction by slip joints inserted on either side. A 30-inch Venturi meter was set near the pumping station in order to give a more accurate record of the amount of water pumped than can be obtained from the revolution counters on the pumps, as was done in the past. A 20-inch Venturi meter at the other end of the main will give a check on any leakage. The valves on the three mains are so placed that any one can be repaired without shutting off more than one section of one of the mains. Mr. Emil Kuichling, M. Am. Soc. C. E., was consulting engineer for the work. The T. A. Gillespie Company, of New York, were contractors for the construction of the main.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xvi, xviii and xxvii.

WATER.

Golden, Colo.—City Attorney W. H. Whitehead writes that at the election held July 3 bonds to the amount of $100,000 were voted for the construction of a municipal system of gravity water works.

Seguin, Tex.—Chas. Troell writes that he and Hugo Troell, both of Seguin, propose to construct an irrigation system and will receive bids Dec. 1 for pumps.

Cheyenne, Wyo.—City Engr. W. D. Pease writes that bids have not yet been asked for the proposed water works improvements to cost $85,000. A. J. Wiley, of Boise, Idaho, Engr. in Charge.

Wilmont, Minn.—It is stated that the Council will receive bids Aug. 5 for the construction of water works from plans prepared by M. B. Haynes, of Mankato. S. L. Long, Village Recorder.

Grand Ropids, Minn.—Bids are wanted July 28 for rebuilding the water works pumping station. Fred. A. King, Village Recorder.

Tell City, Ind.—Bids are wanted Aug. 12 for furnishing and laying a 4-in. cast iron water pipe in Mozart St. H. J. Stuebrk, City Clk.

Dayton, O.—Bids are wanted Aug. 1 for the erection and completion of an extension of the boiler house and pumping station at the water works. Chas. E. Rowe, Secy. Bd. of Trus.

Mt. Pleasant, Mich.—Consulting Engr. W. F. Brown, of Toledo, O., has recommended the boring of additional wells as the best method of obtaining a sufficient supply of pure water for this place.

Chicago, Ill.—Frank Murphy, Contract Clk. of the Dept. of Pub. Wks., writes that the following bids were opened July 11 for constructing one electric traveling crane, capacity 20 tons, at the Chicago Ave. pumping station: Pawling & Harnischfeger, Milwaukee, Wis., $16,500; Whiting Fdy. Equipment Co., Chicago, $11,980 (awarded).

Charleston, S. C.—The plans of the American Pipe Mfg. Co., Philadelphia, which has the contract for designing and building the new works, provide for a timber and earth dam on Goose Creek 11 miles northwest of the city; a pumping station there with a 100-ft. brick stack; one 3,000,000 and two 5,000,000-gal. high-duty pumps; one 5,000,000 and two 3,000,000-gal. low-duty pumps: 600 H.-P. in boilers; a 5,000,000-gal. mechanical filter plant, with a 10,000,000-gal. sedimentation reservoir and a 2,000,000-gal. clear-water basin; a 24-in. cast iron force main to and through the city, 8 miles of distribution mains, 114 hydrants, and the valves and specials needed in the improvement of the piping now in the city. J. W. Ledoux is Ch. Engr. of company.

Jersey City, N. J.—The contract for special casting work in hydrant connections, plugs, caps, bends, manhole heads and covers is stated to have been awarded to the Fagan Iron Wks. Co., of Hoboken, at 3½ cts. per lb.

Kenmore, N. Y.—Engrs. for the Village, Busch Bros., of Buffalo, write that on July 14 the village of Kenmore closed a contract with the Depew & Lake Erie Water Co. for furnishing the village with water. The village will put in its own distributing system and will soon ask for bids. Plans and specifications are now being prepared.

Bellaire, O.—Supt. M. L. Blackburn writes that a vote will be taken on July 28 on the issue of $50,000 bonds for a water works pumping system.

Brookfield, Mo.—City Clk. Chas. K. Hart writes that the contract for constructing water works has been awarded to Jos. Bowers, of Lincoln, Neb., for $6,000. Guaranteed supply, 500,000 gal. per day.

Genesco, Ill.—Bids are wanted Aug. 1 for furnishing 9,000 ft. of 4-in. water main. Henry F. Horft, City Clk.

Lowell, Mass.—A Special Com. of the City Council has under consideration the proposition to supply city water to Dracut and Chelmsford. The estimated cost of mains, etc., is between $20,000 and $50,000.

Lawrence, Mass.—Local press reports state that the Water Bd. will soon let the contract for constructing the dividing walls at the filter gallery. Amount available for this purpose, $5,000.

Ardsley, N. Y.—The Ardsley Heights Water Co. has been incorporated, with a capital of $50,000. Directors: Henry De F. Baldwin, New Rochelle: C. J. Fay, New York, and Wm. Bradley, Philadelphia.

St. Louis, Mo.—Dir. of Works Taylor writes that it is proposed to build, on the World's Fair site, a reservoir having a capacity of 4,500,000 gal. for fire protection and sports.

The House of Delegates has passed the Council bills appropriating $250,000 for a covered reservoir at Baden; authorizing construction of an office, warehouse and stable in the water works pipe storage yard on Eager Road; appropriating $120,000 for work on the new City Hospital pavilions, and authorizing installation of 3 boilers in the Insane Asylum.

Pittsburg, Pa.—Bids are wanted July 31 for installing foundations for 2 15,000,000-gal. pumping engines at the Brilliant Pumping Station. J. O. Brown, City Recorder.

Ithaca, N. Y.—Bids are wanted Aug. 20 for supplying the city with water by hydrants for fire purposes for a period of 5 and 10 years from Dec. 1, 1902. A. G. Marion, City Clk.

Cincinnati, O.—The United States Const. Co. has received the contract for building a brick chimney at the Eastern Pumping Station, for $14,950.

Pomeroy, Wash.—The Council has voted to construct a system of water works to cost $26,500.

Pauls Valley, Ind. Ter.—Bonds to the amount of $25,000 have been voted for water works by a large majority.

Wilmington, O.—City Clk. Lee Baker writes that at the election held July 22 a vote was taken approving the contract between the Council and J. R. Poindexter, of Cynthiana, Ky., for the construction, maintenance and operation of a water works system.

Dickson, Tenn.—The question of constructing water works at a probable cost of $25,000, is under consideration.

Harrisburg, Pa.—Chas. A. Miller, City Clk., writes that the Sinking Fund Comrs. have decided to receive bids about Sept. 1 for $362,000 bonds, which are part of the $1,090,000 improvement loan authorized at the Feb. election. The Bd. of Pub. Wks. is working upon a revised sewer system, a filtration plant, and a dam in the Susquehanna River.

St. Cloud, Minn.—The Industrial Trust Co., of Providence, has declined the offer of the city to purchase the water works plant for $65,000. The company is said to contemplate the installation of a filtering system.

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until Aug. 8 for steam and feed-water piping and filters, galleries and platforms, H. S. Station No. 1. Hiram Phillips, Pres.

Elyria, O.—Bids will be received by the Bd. of Water Wks. Trus. until Aug. 7 for the following work: 4,605 tons of 6 to 20-in. pipe; 25 tons special castings; stand pipe foundation, and stand pipe 30x120 ft. erected; 2 pumping engines, each of 2,000,000-gal. daily capacity, and 2 boilers complete; a submerged crib in Lake Erie, and 1,500 ft. of 24-in. intake pipe and a pump well; for a complete filter plant with a daily capacity of 2,000,000 gal. of filtered water; hydrants, valves, etc., and for laying 40,500 ft. of force main and about 4 miles of distributing pipes. Geo. E. Crisp, Secy.; L. E. Chapin, Consult. Engr., Canton.

Fowler, Colo.—The Town Council has granted to the Crystal Springs Pipe & Water Co. a 20-year franchise to supply the town with water.

Carnegie, Pa.—A Com. of the Council is considering the matter of constructing municipal water works.

Boyne, Mich.—The City Authorities have under consideration the proposition to pipe a water supply from the North Boyne, 3½ miles above the city, at a probable cost of $20,000.

Springfield, Ill.—City Engr. Frank H. Hamilton and Isaac Withrow estimate that an adequate supply of pure water can be secured for this city at a cost of $25,000.

Colerain, Mass.—Press reports state that bids are being received for the construction of water works estimated to cost $5,000.

Dyer, Tenn.—The citizens are said to be considering the construction of a system of water works.

Kenosha, Wis.—The Bd. of Water Comrs., of this city, is said to be considering plans for the building of a large iron standpipe.

Decatur, Ind.—The City Council has passed an ordinance providing for the general installation of meters.

Middleport, N. Y.—The Village Council has granted Dudley & Johnson a franchise to construct, maintain and operate a complete water works system.

Tuscumbia, Ala.—J. W. Northington, of Sheffield, is reported to have received from the City Council a concession for an electric light plant and water works.

Oakland, Cal.—City Engr. Turner estimates the cost of constructing 12th St. dam at $38,000.

Animas, Colo.—It is proposed to construct water works at a cost of $15,000.

Questa, N. Mex.—The Taos Irrigation & Development Co. has been incorporated with a capital of $1,000,000. Headquarters at Questa.

Victoria, Tex.—The question of issuing $7,500 bonds for laying a 12-in. main from the pump house to the standpipe, received a favorable vote at the election held July 15.

Leadville, Colo.—The Colorado Fuel & Iron Co. has purchased 2,000 acres of land in Lake Park, about 7 miles west of Leadville, upon which it is stated the company proposes to construct a storage reservoir for a reserve supply of water for its plant at Pueblo. Proposed dam to be 40 ft. high and 1,000 ft. across.

Kokomo, Ind.—The City Council has given the Kokomo Water Co. a 12-years' extension of franchise.

Elgin, Ill.—Supt. R. R. Parkin writes that the following bids were opened by the Bd. of Water Comrs. on June 25:

For pumping engine, guaranteed duty 115,000,000 ft.-lbs.: Holly Mfg. Co., $11,550 for 2,000,000-gal.; $13,125 for 3,000,000-gal.; $15,540 for 4,000,000-gal.; $18,375 for 5,000,000-gal.; $21,000 for 6,000,000-gal.; $26,250 for two 3,000,000-gal.; $27,090 for one 4,000,000-gal. and one 2,000,000-gal.

A. E. Rutledge & Co. bid for shaft and tunnel complete, including 2,000,000-gal. pumps with pumping engine, all connections to suction from 4 wells, and water and steam connections complete ready for operation, $55,000; for 2 4,000,000-gal. pumps to be driven by 2 compound condensing high-speed engines, $18,000 (awarded). Shaft and tunnel to be readvertised.

Henry R. Worthington bid as follows for pumps driven by Western Elec. motors: A, 6,000,000-gal., 33 H.-P., $7,700; B, 5,000,000-gal., 33 H.-P., $7,450; C, 4,000,000-gal., 36 H.-P., $6,375; D, 3,000,000-gal., 40 H.-P., $5,575; E, 2,000,000 gal., 40 H.-P., $4,800. If General Elec. motors are adopted, the following amounts are to be added: A, $300; B, $250; C, $200; D, $150; E, $150. For generating units, the bids were as follows: Two 11 and 19x16-in. Buckeye tandem comp. engines, $5,700; two 100-Kw. Westinghouse generators, $5,800; total, including condenser, $13,500; two 12 and 24x30-in. cross comp. Allis-Chalmers engines, $7,500; two 100-Kw. Westinghouse generators, $6,400; total, including condenser, $15,900.

Seattle, Wash.—The City Council has been petitioned for water main extensions in the Denny-Fuhrman addition. Estimated cost, $17,000.

Philadelphia, Pa.—Local press reports state that the Dept. of Pub. Wks. is about to receive bids for building according to revised plans, the Lardner's Point pumping station at the Torresdale filtration plant. The lowest bid received last Feb. for this work on the original plans amounted to $1,440,000. The revised plans are said to provide for a plant estimated to cost $7,000,000.

Sterling, Colo.—F. H. Newell, Ch. Hydrographer, Washington, D. C., is said to be in Sterling for the purpose of considering the advisability of recommending to the Government the construction of a reservoir at this point, to irrigate 285,000 acres of Government land in Colorado and Nebraska.

SEWERAGE AND SEWAGE DISPOSAL.

New Albany, Ind.—The Special Com. of the Council appointed to consider the question of sewerage for the city favors a plan for a general system of sewerage. Councilman McQuiddy and City Engr. Coolman are members of the Com.

Syracuse, N. Y.—Bids are wanted July 28 for constructing a 12 and 15-in. pipe sewer in University Ave. and a 12-in. pipe sewer in Butternut St. Geo. J. Metz, City Clk.

Columbus, Miss.—Press reports state that $50,000 bonds have been voted to complete the present sewerage system, build a standpipe, city hall and public school.

Rapid City, S. D.—Citizens are said to be considering the construction of a sewerage system. Jas. Hartgering, Chmn. of Com.

Tacoma, Wash.—An appropriation of $11,000 has been made for the construction of the Edison trunk line sewer.

Elizabeth, Pa.—The Town Council has passed an ordinance for the construction of an 18-in. pipe sewer on Market St. W. F. Taylor, Burgess.

Pittsfield, Mass.—The Common Council has voted against the order adopted by the Aldermen appropriating $8,500 for surface drainage.

McDonald, Pa.—Local press reports state that this Boro. has engaged Trimble & Miller Co., of Pittsburg, to prepare plans and estimates for a sewer system to cost about $50,000.

Brainerd, Minn.—In a recent communication to the Council, Mayor Halsted recommended that the City Engr. be instructed to prepare plans for a complete system of sewerage, and that provision be made at once for putting in sewers.

Duquesne, Pa.—Bids are wanted Aug. 4 for improving 3 streets; also for constructing sewers in 6 streets. S. A. Taylor, Boro. Engr., Pittsburg.
The Boro. is stated to have sold $70,000 bonds, of which $50,000 is for street work and $20,000 for sewer construction.

Glenville, O.—The City Council has passed a resolution for a storm water sewer for streets west of Doan.

Niagara Falls, N. Y.—City Engr. McCulloh estimates the cost of extending the Chasm Ave. trunk sewer at $17,500 to $19,151.

Des Moines, Ia.—According to local press reports the State Bd. of Control has recommended that contracts for sewage disposal plants at 3 State institutions be awarded to the Cameron Septic Tank Co., of Chicago, Ill., as follows: Orphans' Home, Davenport, for $4,450; Mt. Pleasant Insane Hospital, for $7,250; and Industrial School at Mitchellville, for $2,625.

Bluefield, W. Va.—Bids are wanted Aug. 1 for constructing a sewerage system. F. E. Carter, Chmn. Com.

York, Pa.—Bids will be received by John R. Lafean, Chmn. Highway Com., until July 31 for furnishing material for improving the highway with about 10,350 ft. of 20, 24 and 30-in. terra cotta pipe sewer and about 2,090 ft. of 3 and 4-ft. brick sewer. Bids will also be received for furnishing material for paving Highway with about 12,875 sq. yds. vitrified brick paving, 12,000 sq. yds. sheet asphalt, 19,500 lin. ft. of macadamizing and 20,000 lin. ft. of grading.

Swissvale, Pa.—Bids will be received by the Boro. of Swissvale until July 28 for the purchase of $20,000 sewer bonds. R. W. Cummins, Chmn. Finance Com.

Harrisburg, Pa.—Bids are wanted July 31 for constructing a sewer in Pine St. M. B. Cowden, City Engr.

Jamestown, N. Y.—City Clk. Clement B. Jones writes that the contract for extending the sewer system has been awarded to Mahoney Bros. & Gardner. Local press reports gave the estimated cost of this work as about $35,000.

Villisca, Ia.—J. J. Dunnegan, of Shenandoah, Ia., is stated to have received the contract for constructing a sewer system for $6,000.

Stevens Point, Wis.—About 1½ miles of sanitary sewer is about to be built by this city at an estimated cost of $11,000.

Ames, Ia.—The City Council has engaged Prof. A. Marston, of Ames, to draft plans for a complete system of sewers for Ames.

Franklin Falls, N. Y.—The question of extending the sewer system, at a cost of $25,000, is under consideration.

Grinnell, Ia.—Mayor H. W. Spaulding writes that bids will be opened Aug 5 for the construction of a septic tank for sewage disposal; capacity, 250,000 gal. Prof. A. Marston, of Ames, Ia., Engr. in Charge.

Dunkirk, N. Y.—The Council has ordered a sewer in Roberts road, tile, 20-in., about 1 mile long, with earth excavation; also a sewer in Doughty and King Sts., 1,050 ft. long, 15-in. tile, and bids for same will be opened July 29. Plans and profiles on file in office of City Engr.

Jefferson, Ia.—Local press reports state that probably a complete drainage and sewer system will be built in the near future.

Brockport, N. Y.—Thos. Holahan, of Rochester, is stated to have received the contract for constructing the sewerage system. Appropriation, $75,000.

Dike, Ia.—Local press reports state that a sewerage system is to be put in for this place.

Cleveland, O.—Bids are wanted Aug. 5 for constructing sewers in portions of 4 streets. Chas. P. Salen, Dir. of Pub. Wks.

Wyoming, O.—Bids are wanted Aug. 1 for the purchase of $10,000 sewer bonds. W. A. Clark, Village Clk.

West Carthage, N. Y.—Bids are wanted July 31, for constructing a sewer system. W. M. Vincent, Clk. acting Bd. Sewer Comrs.

Beloit, Wis.—Robt. Caldwell, C. E., writes that all bids opened July 7 for 2,700 ft. of 20-in. and 900 ft. 8-in. pipe sewers have been rejected; also that bids will be opened Aug. 8 for 9,000 ft. of 8 to 12-in. pipe sewers.

Cheyenne, Wyo.—City Engr. W. D. Pease writes that it is proposed to build 5,000 ft. of 24-in. pipe sewers, but bids for same have not yet been asked. Probable cost, $15,000.

Wilmont, Minn.—Local press reports state that bids are wanted Aug. 5 for the construction of sewers. S. L. Long, Village Recorder.

Elkhart, Ind.—Bids are wanted Aug. 6 for constructing a 12-in. sewer. Kit McKean, City Clk.

Trenton, N. J.—Bids are wanted Aug. 5 for the construction of sewers in Fall and Warren Sts. C. Edw. Murray, City Clk.

Tecumseh, Mich.—The question of constructing a sewerage system is being agitated.

Mt. Pleasant, Mich.—Willis F. Brown, 55 Law Bldg., Toledo, has completed plans for a main sewer in Dist. No. 7, about 4,000 ft. in length; also plans for dividing the city into sewer districts.

Kansas City, Mo.—City Engr. Robt. W. Waddell writes that W. J. Stevenson & Co. received the contract for constructing a sewer in Sewer Dis. No. 148, for $3,199.

Galveston, Tex.—The Bd. of City Comrs. has decided to lay pipe sewers along Tremont St., work to be done by the city, by day labor, but bids for furnishing to the city vitrified or cement sewer pipe in the following quantities will be received: Aug. 9, 2,000 ft. 36-in., 1,500 ft. 30-in., 700 ft. 24-in., 600 ft. 18-in. and 2,500 ft. 12-in., with Y branches as follows: 60 36-in.x12-in., 50 30-in.x12-in., 40 24-in.x12-in. and 30 18-in.x12-in. Bidders to state prices f. o. b. cars at point of manufacture and prices f. o. b. cars at Galveston. John D. Kelley, Secy. Bd. of Comrs.; C. G. Wells, City Engr.

Hanover, Pa.—Chauncey Ives, of Chambersburg; Wm. McLean, A. C. Huntzinger and others are said to be making arrangements for the building of a sewerage system, with septic tank sewage disposal plant.

Buffalo, N. Y.—Bids are wanted July 31 for constructing 12-in. tile sewers in Trenton Ave., a 10-in. tile sewer in Gesl St. and 20 to 12-in. tile sewer in Cable St. Francis G. Ward, Comr. of Pub. Wks.

Waterbury, Conn.—The lowest bid received July 15 for the storm water conduits and drainage system on Dublin and several other streets was from Patrick F. Sutton at $8,554. The Bd. of Pub. Wks. voted to reject all bids and to receive new bids for above work on Aug. 5. Local press reports state that bids are wanted until Aug. 12 for the extension of the sewer on Benedict St.

Long Island City, N. Y.—Bids are wanted July 31 for constructing 1,984 lin. ft. of 24-in. pipe sewer in Lincoln Ave. (late village of Jamaica). Jos. Cassidy, Pres. Boro. of Queens.

Brooklyn, N. Y.—Bids are wanted July 30 for constructing several sewer basins. J. Edw. Swanstrom, Pres. Boro. of Brooklyn.

Cincinnati, O.—Bids are wanted Aug. 14 for the improvement of Quebec and Jonte Aves. by constructing a trunk sewer and drains. Robt. Allison, Pres. Bd. of Pub. Service.

Carthage, N. Y.—The State Bd. of Health has approved plans for the West Carthage sewer system.

The proposition to construct a $20,000 sewer system for West Carthage carried at the election held July 12.

Sioux City, Ia.—The City Council has instructed City Engr. Lewis to prepare plans and estimates for storm sewers, to cost about $15,000.

New York, N. Y.—One bid only was received July 18 by Jacob A. Cantor for building sewers in Wicker and Van Corlear Places, that of Wm. E. Welch, which has been recommended for award. In detail it is as follows: 215 ft. 3½x2 1/3-ft. brick sewer at $9; 1,260 ft. of 15-in. vitrified pipe sewer, at $6; 60 ft. of 12-in. pipe sewer, at $4; 2 receiving basins, at $200; 1 gully trap, at $300; 1,925 cu. yds. rock excavation, at $4, and 4 M. ft. timber, at $40; total, $18,295.

BRIDGES.

Oswego, N. Y.—It is stated that a committee has been appointed to estimate the cost of repairing the old bridge and also the cost of a new structure. F. W. Ormsby, City Engr.

Glenolden, Pa.—Press reports state that the Philadelphia, Wilmington & Baltimore R. R. has offered to place a bridge over the tracks at Ashland Ave. W. H. Brown, Chief Engr.

St. Marys, O.—The Toledo & Ohio Central Ry., it is reported, will build a bridge over the canal in St. Marys. C. Buxton, Chief Engr.

Cincinnati, O.—Press reports state that Co. Engr. Krog has submitted to the Co. Comrs. specifications for a $200,000 bridge over the Big Miami River near Elizabethtown. Cost of approaches, $49,385; superstructure and roadway, 586 ft. long, $115,000.

Oshkosh, Wis.—Press reports state that Ericson & Lehman, of Chicago, Ill., are preparing plans for a 50-ft. concrete and steel bridge, to be built in this city at a cost of $10,000.

Rutledge, Tenn.—It is stated that the Co. Court has voted to build an $80,000 bridge across Holston River, and that the contract for construction will probably be let the middle of August.

Harrisburg, Pa.—The Bd. of Viewers appointed to report on the condition of the Millerstown bridge across Juniata River, which was destroyed by fire June 10, report that the bridge, including the abutments and piers has been destroyed, and recommend replacing it with a $92,000 structure.

Pleasanton, Cal.—The Co. Bd. of Supervisors has adopted plans prepared by the Co. Surveyor for the construction of a concrete bridge across Arroyo del Valle Creek, north of Pleasanton, estimated to cost $12,000.

Cayuga, Ind.—The proposition to construct a $12,000 bridge across Wabash River, this city, has, according to reports, carried.

St. Marys, O.—The Massillon Bridge Co., Massillon, O., is reported to have secured the contract to construct a bridge at South St. for $5,200.

Rome, N. Y.—Bids will be received by Chas. S. Boyd, Supt. of Pub. Wks., at his office in the Capitol at Albany, N. Y., until July 30 for constructing a bridge across the Erie Canal at So. James St., Rome.

Tell City, Ind.—Bids are wanted by the Bd. of Co. Comrs. until Aug. 4 for constructing a bridge 101 ft. long and 14 ft. wide. Albert P. Fenn, Co. Aud.

Germania, Wis.—Bids are wanted July 29 for constructing 2 stone abutments for a bridge to cross the south branch of Embarrass River at the Swanke Mill site (section 13), town of Germania. Address H. W. Mueller.

Atlantic City, N. J.—Bids are wanted Aug. 6 for the construction of 3 bridges on the county road near Weekstown. For specifications address John T. Irving, Elwood, N. J.

Boston, Mass.—Ch. Engr. Wm. Jackson writes that the following bids were opened July 17 by the Cambridge Bridge Comn. for building 2 masonry abutments for Cambridge bridge. Bidders all of Boston: Holbrook, Cabot & Rollins, $168,000 (awarded); Patrick McGovern, $170,250; Jones & Meehan, $174,800; Lawler Bros., $176,316. The pile and concrete foundations are, each, 61½x170 ft. long; materials, about 15,000 cu. yds. concrete, 1,000 cu. yds. granite, and 4,200 piles. Work is to be completed by Aug. 1, 1903.

Logansport, Ind.—Bids are wanted Aug. 5 for repairing an iron bridge in Tipton Township and for constructing a stone arch culvert in Miami Township. J. G. Powell, Co. Aud.

Elmira, N. Y.—Bids are wanted July 31 for building abutments for bridges across Hoffman Creek at 1st and 3d Sts. M. H. Murphy, Clk. Bd. of Pub. Wks.

McCook, Neb.—Bids are wanted Aug. 5 for furnishing all material and constructing a bridge across Republican River. E. J. Wilcox, Co. Clk.

Coffeeville, Miss.—Bids are wanted Aug. 4 at the Chancery Clerk's office in Water Valley, for the building of several bridges in Yalobusha County. J. D. Halle, Clk.

Boston, Mass.—Bids are wanted Aug. 4 for building abutments and approaches for Wellington Bridge, Middlesex Fells Parkway, Somerville and Medford. Wm. T. Pierce, Engr. Metropolitan Park Comn.

Glenwood, Ia.—It is reported that the Mills Co. Bd. proposes to build an iron bridge west of the town.

Allegheny, Pa.—Press reports state that an ordinance has been passed by the Select Council for rebuilding and relocating the Superior Ave. viaduct over the R. R. tracks from California Ave. to Pacific Ave., with approaches on Preble Ave. and W. Market St.

Stockton, Cal.—Local press reports state that the contract for the McMullen Lake bridge was awarded to M. B. White for $13,144.

Gallipolis, O.—It is reported that the lower iron bridge has collapsed.

Sullivan, Ill.—Press reports state that an iron bridge will be built across the Okaw east of town by Sept. 1. Main span, 60 ft. Approaches, 50 ft. and 16 ft.

Cedar Falls, Ia.—The Cedar Falls & Waterloo Rapid Transit Co. is reported to have estimated its loss due to floods at $15,000 to $18,000. The bridge crossing Dry Run is the heaviest loss.

Emporia, Kan.—The Lyon Co. Comrs. are being petitioned for two bridges across the Cottonwood, one south of the poor farm and one in the Fowler settlement, 2 miles east of the Columbia Ford bridge. Cost of each, $6,000 or $8,000.

Sault Ste. Marie, Mich.—Press reports state that the Co. Bd. of Superv. has granted the petition of Drummond Township to construct a bridge across Pottaganissing River. It is also reported that Road Comr. Splan is making an estimate of the cost of replacing Co. bridges with steel structures.

Philadelphia, Pa.—The Bureau of Highways is reported to have set aside $65,000 for repairing and building bridges.

Dyersville, Ia.—The Bd. of Superv. is considering the matter of replacing the bridge over the Maquoketa River with a 168-ft. single span steel bridge at a cost of about $5,000.

Greensburg, Pa.—Petitions are being circulated for a joint Co. bridge over the Monongahela between the towns of Donora and Webster.

Hanford, Cal.—The Kings Co. Supervisors are considering building 2 bridges over Kings River and New River.

Fresno, Cal.—Local press reports state that Fresno Co. will construct a road connecting Laton with the road leading north from Hanford, bridge Old Dutch John Cut, and continue the road to connect with the Selma thoroughfare.

Mitchellville, Ia.—The bridge over Skunk River, 3 miles north of town, is reported washed away.

Colesville, N. Y.—The $22,000 issue of bonds of the town of Colesville to pay for a bridge to be built at Nineveh is reported purchased by the Binghamton Savings Bank.

Boone, Ia.—It is reported that several thousand dollars' damage has been done to the Boone viaduct by flood.

Akron, O.—Press reports state that the City Council has under consideration the erection of a viaduct across Mill St.

Omaha, Neb.—Local press reports state that City Engr. Rosewater and Chief Engr. J. B. Berry, of the Union Pacific, have come to an agreement in regard to building two viaducts, one at Martha St. at the intersection of the U. P. and Burlington tracks to cost $50,000, and one crossing the U. P. tracks at Capitol Ave. and 8th St. to cost $30,000. The plan will have to receive the indorsement of Pres. Burt and the City Council before definite preparations are made.

Ann Arbor, Mich.—Press reports state that $25,000 will be needed to rebuild 7 culverts damaged by flood.

Luray, Va.—It is stated that an iron bridge will be constructed across the creek in Luray. Span, 100 ft.; width, 18 ft.

Greenville, Pa.—Press reports state that the Mercer Co. Comrs. will build an iron bridge over the river at Main St. Cost, $12,000.

Somers, Conn.—It is reported that a steel bridge 65 ft. span and 25 ft. wide will be built over the Scantic River by the town.

Columbus, O.—It is reported that the contract for the Hayden Run bridge was not legally let, and will have to be readvertised for.

Syracuse, N. Y.—Local press reports state that the D., L. & W. R. R. has agreed to the building of the Butternut St. bridge across the Oswego Canal and the doing away with the coal sheds at that place. To be an overhead steel girder bridge. Cost of improvement, $12,000; city to pay $5,000.

Ft. Plain, N. Y.—It is reported that State Supt. of Pub. Wks. Boyd has awarded the contract for construction of a bridge over Osaquago Creek to the Owego Bridge Co. for $6,822.

Joliet, Ill.—It is reported that the Highway Comr. proposes to replace the Red Mill bridge with a concrete arch.

Sonyea, N. Y.—See "Public Buildings."

Cleveland, O.—Press reports state that Supt. of Track Elev. Breen considers two more viaducts necessary, one near Hoppie St., Cumminsville, and the other over Wood St. near the entrance of the Grand Central Depot.

PAVING AND ROADMAKING.

Memphis, Tenn.—Of the 14 streets ordered paved by the City Council on May 8, it has been decided to lay asphalt on 10 streets, brick on 2 streets, gravel and block stone on the other 2 streets. Amount available for this work, $225,000. J. J. Williams, Mayor. A. T. Bell, City Engr.

Worcester, Mass.—Both branches of the City Council on July 21 passed, almost unanimously, the order for a loan of $80,000 for the paving of Main St. with granite block.

Boston, Mass.—Jas. Donovan, Supt. of Streets, has placed the estimated cost of repaving a portion of Albany St. with granite block at $56,700.

Buffalo, N. Y.—Bids will be received by the Dept. of Pub. Wks. until Aug. 5 for paving a portion of South St., and for repaving portions of Clinton St.; also for macadamizing a portion of Parkside Ave. Francis G. Ward, Comr. Pub. Wks.

Tyrone, Pa.—Bids will be received by the Boro. Highway Com. until July 29 for block pavement on 10th St., requiring about 3,700 sq. yds. of paving. W. Fisk Courad, Chmn.; J. Luden Henry, Boro. Engr.

New York, N. Y.—Bids are wanted Aug. 4 for repaving with asphalt on present block pavement the roadway of Forest and Park Aves., requiring 41,665 sq. yds. asphalt pavement, including binder course; 41,775 sq. yds. old stone pavement to be relaid as foundation, etc.; 17,550 lin. ft. bluestone curbing, furnished and set, and 5,700 lin. ft. of old curbstone, rejoined and reset; for repaving with asphalt on a concrete foundation the intersections of several streets, requiring about 3,700 sq. yds. of asphalt, including binder course, and for paving with asphalt on a concrete foundation a portion of Washington Ave., requiring 65,300 sq. yds. of asphalt, including binder course; 11,250 cu. yds. concrete, 28,800 lin. ft. of old curbstone, rejoined when necessary and reset. Louis F. Haffen, Pres. Bronx Boro.

Bids are wanted July 29 for regulating and repaving with asphalt pavement on present pavement relaid as foundation the roadways of numerous streets; the engineer's estimates call for 64,830 sq. yds. of asphalt in all. Bids are also wanted at the same time for regulating and repaving with granite block on concrete foundation the roadways of 2 streets, in all 3,570 sq. yds. of paving. Jacob Cantor, Boro. Pres.

Cincinnati, O.—Bids are wanted Aug. 19 for improving a portion of Beekman St. by grading, setting granite curbs and crossings, and paving the roadway with granite block. Geo. F. Holmes, Clk. Bd. Pub. Service.

Cleveland, O.—The County Comrs. have sold bonds to the amount of $91,000 for Kinsman Road improvement.

Erie, Pa.—An ordinance before the Council provides for the issue of $7,700 bonds for the repaving of a portion of 4th St.

Oakland, Md.—Bonds to the amount of $8,000 are said to have been authorized for paving purposes.

Bushnell, Ill.—The Council is said to be preparing to pave several streets.

Arcola, Ill.—Press reports state that Locust St. is to be paved at a cost of $15,000.

St. Paul, Minn.—The Com. on Roads & Bridges of the Bd. of Co. Comrs. estimate $35,000 as the amount required for the current year.

Frederick, Md.—The estimated cost of repaving with brick 2 blocks on E. Church St. is placed at $10,000.

Boise City, Idaho.—Local press reports state that on July 31 bids will be received for furnishing a 12-ton steam roller, a rock crusher, capacity 10 to 20 tons, and a 24-in.x6-ft. revolving screen.

It is proposed to pave S. 8th St., probably with brick.

Mt. Gilead, O.—Plans for paving Marion St. have been approved by the Council.

Louisville, Ky.—The City Engr. has been instructed to prepare plans for macadamizing and paving with granitoid, Mechanic, Graham and Fulton Sts.

Newark, N. J.—The Bd. of Wks. has passed ordinances for the paving of several streets.

Knoxville, Tenn.—The Jefferson Co. Comrs. have decided to build an additional 10 miles of pike road to be located on the Maryville line, extending southwest from Dandridge.

Jersey City, N. J.—The Bd. of Finance has received a petition for the repaving of Grand St. from Hudson St. to Pacific Ave., with granite block. Estimated cost, $97,546.

Beaumont, Tex.—Local press reports state that Calder Ave. is to be paved for its entire length.

Decatur, Ill.—Local press reports state that W. Main St. is to be paved with asphalt to the west end of the University grounds.

Jamestown, N. Y.—City Clk. Clement B. Jones writes that a portion of Forest Ave. is to be paved with brick.

Chester, N. Y.—Street improvement bonds to the amount of $16,800 are stated to have been sold.

Williamsport, Pa.—The Highway and Sewer Committees are about to let a contract for paving Park St., at a cost of $5,700.

Memphis, Tenn.—The sum of $15,000 has been guaranteed by certain citizens toward the paving of Central Ave. with asphalt, for a distance of about 2 miles.

Bloomington, Ill.—City Engr. Elmer Folsom writes that asphalt pavement is to be laid on Monroe and Jefferson Sts., also on Colton and Towanda Aves., in all about 9,000 sq. yds.

St. Marys, O.—Bids are wanted Aug. 9 for furnishing material, grading, curbing with stone and paving with brick or sheet asphalt, portions of Wayne St. J. H. Rowe, Jr., Clk.

York, Pa.—See "Sewers."

Cleveland, O.—Bids are wanted Aug. 13 for grading, draining, curbing and paving portions of Petrie St. with Medina dressed block stone on a 6-in. concrete foundation. Chas. P. Salen, Dir. of Pub. Wks.

West Hoboken, N. J.—Bids will be received by the Town Council until July 30 for paving High Point Ave. John P. McMahon, Town Clk.

Thompson, Conn.—Bids will be received by the Bd. of Selectmen until July 28, for grading and macadamizing a section of road in this town. Oscar Tourtellotte, Chmn. Bd. of Selectmen.

Philadelphia, Pa.—Local press reports state that the following bids were opened July 22 for paving about 5 or 6 miles of streets with asphalt, and for repaving about 10 miles with asphalt: Vulcanite Paving Co., from $2.54 to $2.59 per sq. yd. for new paving, and $2.28 to $2.57 for repaving; Pennsylvania Asphalt Paving Co., $2.52 to $2.61 for new, and $2.43 to $2.59 for repaving.

Little Rock, Ark.—The City Council has passed an ordinance appropriating $30,000 for the paving of W. Markham St. with asphaltum.

Seattle, Wash.—The City Engr. estimates the cost of proposed brick paving on Union St. at $70,000.

Charleston, W. Va.—Street paving bonds to the amount of $70,000 were authorized at the election held July 21.

Duquesne, Pa.—See "Sewerage and Sewage Disposal."

Dorchester, Mass.—Bids will be received by Jas. Donovan, Supt. of Streets, until July 30, for constructing a macadam road on Moultrie St.

Vincennes, Ind.—It is stated that bids are wanted Aug. 15 for constructing about 22 miles of gravel roads in Washington Township. J. D. Williams, Co. Aud.

Fort Sheridan, Ill.—It is stated that bids are wanted Aug. 12, for constructing macadam road at the military reservation. Col. E. B. Atwood, Chmn. Q. M., Chicago.

Newport, Ind.—Bids are wanted Aug. 19 for constructing gravel roads in Clinton Township, in all about 22 miles. Wm. P. Bell, Co. Aud.

Trenton, N. J.—Bids are wanted Aug. 5 for the paving of a portion of East Front St. with sheet asphaltum over Belgian block. C. Edward Murray, City Clk.

Local press reports state that the Common Council proposes to expend $35,000 in repairing and repaving with sheet asphaltum the principal streets in the center of the city.

Indianapolis, Ind.—Bids are wanted Aug. 4 for improving certain alleys by paving with brick. Harold C. Megrew, Chmn. Bd. of Pub Wks.

Verona, Pa.—Bids are wanted July 28 for grading several streets, in all 39,000 cu. yds. Frease & Sperling, Boro. Engrs.

Duluth, Minn.—Bids are wanted by the Town Bd. of Superv. until Aug. 1 for building ½ mile of wagon road in sections 33 and 34, in town 53, range 12. R. S. Postal, Town Clk., Molde, Minn.

Ocean City, N. J.—Bids are wanted July 28 for the purchase of $85,000 street improvement and fire bonds. Ira S. Champion, City Treas.

Ft. Scott, Kan.—City Clk. J. O. Brown writes that in the near future contracts will be let for 25 blocks of vitrified brick paving. U. S. Stoner, City Engr.

Beloit, Wis.—The Bd. of Pub. Wks. is planning to pave portions of School St., Prairie Ave., C, E and Bridge Sts. with brick and macadam. Probable cost about $60,000.

Marshalltown, Ia.—The City Council proposes to pave S. 3d Ave. with 1 course of brick upon old macadam, about 8,600 sq. yds. paving and 5,000 ft. of curbing. Wm. Bremner, City Engr.

Ashland, Wis.—City Engr. M. T. Dozer writes that the Bd. of Pub. Wks. will receive bids Aug. 7 (readvertisement) for macadamizing certain streets, in all 8,970 sq. yds., with 2,250 cu. yds. of excavation and 4,000 lin. ft. of curb.

Kansas City, Mo.—City Engr. Robt. W. Waddell writes that asphalt paving contracts, for which bids were opened July 16, have been awarded as follows: To Barber Asphalt Paving Co., Lydia Ave., at $2.15 per sq. yd., also Woodland Ave., at $2.15; to Parker-Washington Co., Illinois Ave., at $2.15 per sq. yd.

East Grand Forks, Minn.—Recorder Henry Harm writes that the bids for paving to have been opened July 15, as stated in The Engineering Record of July 5 have been laid over until Aug. 5, an error in the advertising necessitating this delay. There will be about 33 blocks of paving, material not decided; bidders may bid on any kind of material, but will have to furnish their plans and specifications.

Galveston, Tex.—The Bd. of City Comrs. has decided to pave a portion of Tremont St. with brick, 7,094 sq. yds., work to be done by the city by day labor. Bids for furnishing to the city 500,000 best quality vitrified brick of standard size will be received until Aug. 9, delivery to begin within 30 days from date of contract; bidders to state prices f. o. b. cars at point of manufacture; also prices f. o. b. cars at Galveston. Jno. D. Kelley, Secy. Comrs.; C. G. Wells, City Engr.

Lowell, Mass.—The Common Council has passed an order appropriating $38,390 for the paving of several streets with asphalt.

Atchison, Kan.—On July 14 the Council passed a resolution declaring it necessary to grade, pave with brick and curb with cement Division St. Fred Giddings, City Engr.

Lead, S. D.—City Aud. S. E. Crans writes that in about 60 days bids will be received for 1 mile of brick for stone paving. J. P. Crick, City Engr.

POWER PLANTS, GAS AND ELECTRICITY.

New Castle, Pa.—Regan & Muliock, of Philadelphia, are stated to have received the contract for building the municipal conduit system. The cost to be $40,908; all telephone, telegraph and electric light wires, on the main streets, to be buried.

Livingston, Mont.—E. Goughnour has asked the City Council for a franchise to install an electric light plant, and erect poles on the streets.

Tucson, Ariz.—Press reports state that the Electric Light & Power Co. proposes to add a new gas plant to its works.

Roswell, N. M.—The Roswell Electric Light & Power Co., of Roswell, has been incorporated by Carl Morris Bird, Chas. F. Bode, of Roswell, and others. Capital, $40,000.

Reading, Pa.—The Reading Power Co. is stated to have been organized by Robt. N. Carson, Henry C. Moore and Edw. J. Moore, of Philadelphia, and others, for the purpose of building a $1,000,000 plant, to supply this city and other towns and boroughs in the county, with light and power.

Winnsboro, S. C.—Bonds to the amount of $10,000 have been voted for a municipal electric light plant.

Plainwell, Mich.—The Plainwell Construction Co., capital $50,000, and the Plainwell Power Co., capital $100,000, have been organized to develop water power along the Kalamazoo River, especially at Plainwell and Allegan.

West Seneca, N. Y.—The West Seneca Light, Heat & Power Co. has been incorporated with a capital of $200,000. Directors: E. B. Smith, C. A. Hahl and H. N. Kraft, of Buffalo.

Paducah, Ky.—See "Electric Railways."

York Haven, Pa.—The York Haven Water & Power Co., through Pres. Carter and Judge Stewart, has awarded the contract, for the erection of the transforming station in West Manchester Township, on the northern extremity of Jackson Ave., to Spangler & Bro., of East York, Pa. According to plans prepared by J. A. Dempwolf, of York, the structure will be 90x56 ft., with an annex 34x23 ft., all of fireproof construction.

Natchez, Miss.—The Natchez Light, Heat, Power & Transit Co. has been reorganized, and it is stated that extensive improvements will be made to the plant and its equipment. A. G. Campbell, Pres.; E. H. Ratcliff, Vice-Pres.; Marshall Gaither, Secy.; A. N. Jacobs, Treas. and Gen. Mgr.

Kalamazoo, Mich.—Frederick N. Rowley, of Kalamazoo, and Wm. A. and Jas. B. Foote, of Jackson, are stated to have formed a company, with $50,000 capital stock, to control the water power of southwestern Mich., and furnish electricity for projected interurban roads, and for lighting.

Jackson, Miss.—Local press reports state that the Capitol Comrs. propose soon to let contracts for the erection of the power plant and the wiring of the new Capitol; also for grading and improving the grounds. The two contracts, which will be let separately, will amount to about $80,000.

Lansing, Mich.—The Grand River Electric Co. has been organized at Lansing to build a dam at Delta, 6 miles from Lansing on Grand River, for the purpose of furnishing electricity for heat, lighting and power in Lansing. Capital stock of $50,000. It is expected to generate between 1,000 and 1,500 H.-P. S. E. Jarvis, of Lansing, and Glen D. Smith, of Jackson, are said to be the principal incorporators.

Rockport, Mich.—Articles of association have been filed by the Rogue River Electric Light & Power Co., organized for the purpose of furnishing this village with electricity.

Stromsburg, Neb.—J. B. Buckley and F. E. Holden are reported to have formed a company to build a $15,000 electric light plant.

Decatur, Ind.—The Decatur Oil & Gas Co. has asked for franchise for the purpose of piping gas through the streets.

Marietta, O.—The Union Natural Gas Co. has been formed, with a capitalization of $6,000,000 and an authorized short term bond issue of $2,000,000. The new company has absorbed the gas properties of T. N. Barndall in W. Va. and Ohio. A pipe line will be laid from the Lewis field in W. Va., and other lines will be laid in the Ohio field. The company was organized by R. C. Hall & Co., stock brokers. Mr. Barndall is said to be a heavy stockholder.

Bellefontaine, O.—The City Council has passed a resolution appropriating $15,000 for the improvement of the gas works.

Riverside, Cal.—The City Trustees have under consideration a proposition from Prof. C. G. Baldwin to sell to the city his water right in Mill Creek Canyon, including an extensive raft for $50,000; he estimates that a plant adequate to develop the power from this water supply would cost about $200,000. The proposition to issue $300,000 bonds (the additional $50,000 to be used in extending the present system) may be submitted to a vote of the people.

Gallipolis, O.—City Clk. Geo. F. Bovie writes that a franchise has been granted to Maxon & Eysenbach, of Coshocton, O., for constructing an electric light plant and furnishing the city with light for a period of 10-years, their bid submitted July 15 being as follows: $52.75 per arc lamp per annum, moonlight schedule: 50 16 c.-p. incandescent lamps at $5 per lamp per annum.

Bennettsville, S. C.—Bids are wanted Aug. 15 for the purchase of $12,000 electric light bonds. J. M. Jackson, Chmn. Bd. of Pub. Wks.

Beaver, Utah.—Bids are wanted by the Majestic Co., W. M. White, Engr., until Aug. 1 for the construction of the 3 lower dams, to develop 1,800 H.-P. (approximate cost $50,000), for the power plant in Beaver Canyon. The dimensions of the dams are given as follows: Dams Nos. 1 and 2 will be 290 ft. long, 300 ft. thick at the base, 10 ft. thick at the top and 76 ft. high; dam No. 3 will be 144 ft. thick at the base, 10 ft. at the top and 36 ft. high. Mr. Lewis is Pres. of the Co.

Willows, Cal.—Bids are wanted Aug. 11 for a franchise to supply this town with electric power and light as applied for by the Northern Cal. Power Co.

Elkton, Md.—The Elkton Gaslight Co. proposes to erect, in the near future, a 25,000 ft. holder; also to extend its mains.

Postville, Ia.—Town Clk. Wm. Shepherd writes that on July 14 it was voted to grant a franchise for a gas plant.

Chicago, Ill.—The Chicago, Milwaukee Ave. & Inland Lakes Traction Co., of Chicago, has been incorporated, with a capital of $50,000, to operate street railway, light, heat and power plant. Incorporators: S. A. Walther, J. A. Walther and G. F. Lanaghan.

Cleveland, O.—The Council is stated to have passed the ordinance providing for the placing of all wires in the city underground, within 2 years.

Joliet, Ill.—A trust deed for $1,000,000 is stated to have been filed by the Joliet Gaslight Co. to secure funds for the erection of a new plant in this city and the extension of the present system.

Pontiac, Ill.—Press reports state that the Home Gas Co. has secured a 30-year lease on property on Sanderson Ave., and will at once commence the erection thereon of a gas and electric plant, the company to be capitalized at $100,000.

Norristown, Pa.—The County Comrs. have awarded contracts for work on the court house as follows: Heating and ventilating to Wm. Miller & Sons, their bid being $14,000, with motors, etc., and $13,575 without motors; lighting with electricity, to E. P. Strong & Co., their bid being $7,061, with fixtures, etc., and $4,629 without fixtures.

The Council has passed an ordinance granting to the Norristown Steam Heating Co. the right to lay conduits and pipes for the general heating of houses, etc.

Washington, D. C.—The Walter Motor & Power Co. has been incorporated at Wilmington, Del., with a capital of $1,000,000. Incorporators: Wm. L. Walter, of Port Huron, Mich.; Sam. W. Smith and Edgar Weeks, of Michigan; Burtt H. Rockway and Hopewell H. Darneille, of Washington, and others. Washington office of Co., 313 John Marshall Pl., N. W.

Trinidad, Colo.—The City Council has passed ordinances granting to Seth Hartley a franchise for the construction of an electric railway connecting Trinidad with the towns Starkville and Sopris, and an ordinance granting to him a 5-year franchise for lighting the city with electricity, provided the road is built.

Los Angeles, Cal.—Local press reports state that Pres. John B. Miller, of the Edison Electric Co. confirms the sale by his corporation of $10,000,000 bonds, the money to be used in betterments and general expansion. Of the sum, $3,000,000 will be available at once, and $7,000,000 will be on call for use in the next 5 years.

Baker City, Ore.—A. B. Frame, of Portland, is making surveys for the flumes and building of the proposed power plant; the City Council, of Baker City, some time ago granted Mr. Frame an electric light franchise.

Rushford, Minn.—Bids will be received by C. O. Alm, City Clk., until Aug. 15, for the purchase of $7,000 electric light bonds.

Springfield, Mass.—It is stated that the Springfield Gas Co. has asked permission to increase capital stock by $250,000, to pay for additions to plant and pipe lines.

Romeo, Mich.—Bids will be received by the Bd. of Electric Light Comrs. until Aug. 7 for erecting a brick chimney with a 3-ft. 6-in. flue. Byron N. Seaman, Clk.

Beaumont, Tex.—The Eclipse Power Co., of Beaumont, capital stock $10,000, is reported incorporated by D. O. Lurly, H. R. Decker and others.

Broad Brook, Conn.—The Broad Brook Mill Co. is contemplating the installation of an electric plant to furnish 1,200 lights in the mill.

Columbus, O.—The Citizens' Lighting & Heating Co., of Columbus, is reported incorporated, with $10,000 capital stock, by J. W. Barber, J. D. Karns and others. The purpose is to furnish electric light and hot water heating.

St. Cloud, Minn.—A. G. Whitney, of the Sauk Rapids Power Co., St. Cloud, writes that he proposes to construct a water power dam at Sauk Rapids. Probable cost, $85,000 to $100,000.

Detroit, Mich.—Bids will be received by the Pub. Lighting Comr. until Aug. 29 for furnishing one 900-H.-P. engine, one 600-Kw. alternator, one 60-Kw. exciter and 320,000 pairs carbons.

Bordentown, N. J.—The Bordentown Electric & Motor Co. has filed an amended certificate of incorporation, which enlarges its scope to include the furnishing of power to the Camden & Trenton Ry. for several counties in this and other sections of the State. Dr. J. S. Gilbert is Supt. of both companies.

Chicago, Ill.—The Power House of the Consolidated Traction Co., at Ridgeland Ave. and Lake St., is reported to have been damaged by fire.

Massena, N. Y.—The St. Lawrence River Power Co. has been incorporated with a capital of $7,000,000. The directors are Henry P. Davison, of Englewood, N. J.; Mark T. Cox, of East Orange, N. J.; Samuel E. Porter, of New York, and others.

Tuscumbia, Ala.—See "Water."

York, Pa.—The plan to develop the water powers near McCall's Ferry, on the lower Susquehanna River, is now promised fulfillment by the formation of a syndicate by the Continental Trust Co., of Baltimore, controlling the United El. Lt. & Power Co., of Baltimore, and the Mt. Washington El. Co.

Niagara Falls, N. Y.—The Ontario Power Transmission Co. (directors, Jno. J. Albright, Edmund Hayes and Geo. S. Field, of Buffalo, and J. S. Simmons and S. P. Franchot, of Niagara Falls), has applied for a franchise to distribute current through the city from a water power plant to be developed at the Dufferin Islands, on the Canadian side of the river.

ELECTRIC RAILWAYS.

Nashville, Tenn.—Surveys are being made under the supervision of Prof. C. F. Brown, of Vanderbilt University, for 17 miles of the road, to be in all 53 miles long, which is to be built by the Nashville & Lewisburg El. Ry., from Nashville to Lewisburg.

Kalamazoo, Mich.—See "Power Plants, Gas and Electricity."

Annapolis, Md.—The Washington, Baltimore & Annapolis El. R. R. has asked the City Council for franchises to enter the city by way of Northwest St.

Cincinnati, O.—The Cincinnati, Milford & Goshen St. Ry. Co. has amended its charter so as to enable it to construct lines in Epworth Heights and Madisonville.

Hamilton, O.—The Cincinnati, Hamilton & Indiana Traction Co., through J. C. Hooven, its Pres., made application to the Butler County Com. for a 50-year franchise between here and College Corner, O. The right of way between Darrtown and Oxford, however, is through private property.

Mineola, L. I., N. Y.—A certificate has been filed with the Sec. of State, announcing the consent of the State Bd. of R. R. Comrs. to the building of the Nassau Co. Ry. Co.'s projected road. Local consent has yet to be obtained.

Newburgh, N. Y.—Articles of incorporation have been filed by the Intervale Traction Co., of Newburgh. The company is capitalized at $300,000, and is to construct an electric railroad 28 miles in length from Newburgh to Goshen. The directors are: Hiram B. Odell and J. A. P. Ramsdell, of Newburgh; Chas. W. Griffith, New York, and others.

Watertown, N. Y.—The Black River Traction Co. is said to be planning to make extensions to its line.

Mechanicville, N. Y.—The Hudson Valley Ry. Co. is said to have in contemplation the construction of a dam across the Hudson and the acquisition of sufficient water power to operate the Mechanicville & Stillwater Div. of the road and to transmit power to the other divisions of the road if necessary. J. H. Armstrong, Ch. Engr., Glens Falls, N. Y.

Texarkana, Ark.—The City Council has granted a franchise to Geo. W. Baumoff, of St. Louis, Mo., for the construction of an electric street car line.

Lafayette, Ind.—John P. Smith & Co. have filed with the Co. Aud. a petition asking for a franchise to operate their electric line in this county.

Syracuse, N. Y.—The Rapid Transit Ry. Co. is said to have in contemplation the construction of a 2-mile extension of the South Ave. line through the southwestern part of the city. Estimated cost of said extension $30,000; E. G. Connette, Gen. Mgr.

Hamilton, O.—Falke Bros., of Milwaukee, Wis., are reported to have been given the contract to grade, build and equip an electric road 48 miles in length from Hamilton, O., to Richmond, Ind. Gus N. Hodges, of Dayton, O., is said to be the chief promoter.

Alexandria, La.—B. Willard, Gen. Mgr., and F. S. Hunn, Asst. Mgr. of the Gen. Electric Co. at Atlanta, Ga., are said to be interested in the proposed construction of an electric car line for this city.

Mt. Vernon, N. Y.—The Bd. of Aldermen has given permission to the New York & Port Chester R. R. Co. to construct its rapid transit system through Mt. Vernon.

Morrisville, Pa.—The Council has passed an ordinance granting a franchise to the Phila., Bristol & Trenton St. Ry. Co.

Augusta, Me.—Articles of association have been filed for two new electric railroads—the Augusta & Oakland and the Augusta & Waterville. The former road will extend from this city through the Belgrade lakes region, to Oakland. The other will run from Augusta, on the east side of the river, through Riverside, North Vassalboro and Winslow to Waterville. The incorporators of both companies are: Thos. J. Lynch, Dr. Fred G. Kinsman, of Augusta; Fred S. Thorne, of Gardiner, and others. Each concern has a capital stock of $200,000.

San Jose, Cal.—Lewis A. Sage, of San Jose, is stated to have obtained a 50-year franchise to build and operate an electric railway joining Saratoga, Los Gatos and San Jose, and according to local press reports bids will probably be received Aug. 18.

Middlefield, O.—A. E. Hunt and W. D. Gray, of Orangeville, O., are said to be interested in the proposed construction of an electric railway from Middlefield, O., to Sharon, Pa., via Mesopotamia, Bloomfield, Greene, Gustavus, Kinsman, Orangeville and Byerly's Corners.

Norristown, Pa.—The Council has passed an ordinance granting to the Norristown Passenger Ry. the right to lay its tracks and operate same on certain streets in this Boro.

West Middlesex, Pa.—The East End St. Ry. Co., of Sharon, has been granted a franchise for a street railway through West Middlesex. The Co. will ask for a franchise from the Wheatland Council.

Great Barrington, Mass.—The incorporators of the New York & Berkshire St. Ry. Co. held a meeting at Great Barrington recently and perfected the organization of the company by electing officers, etc. The proposed line is from New York State line in the town of Mount Washington to the Connecticut River at Springfield, a distance of 65 miles. Pres., R. C. Taft, of So. Egremont; treas., W. C. Dalzell, of So. Egremont; sec., O. C. Bidwell, of Great Barrington, Consulting Engr., H. F. Keith, of Mount Washington.

New Orleans, La.—The St. Charles St. R. R. Co. is stated to have sold $75,000 bonds for the contemplated extension of the road to Walnut St. E. B. McKinney, Ch. Engr.

Riverside, Cal.—The San Bernardino Valley Traction Co. has asked the City Trustees for a franchise for an electric car line from the boundary of San Bernardino Co. on Colton Ave. to the city limits. Bids for the purchase of this franchise will be received Aug. 19.

Utica, N. Y.—The Utica & Mohawk Valley Ry. Co. has filed with the Co. Clerk of Oneida and Madison Cos. maps, etc., with notice of extension (9 miles in length) of the proposed line from Oneida to Sylvan Beach.

Vincennes, Ind.—The Southern Indiana Traction Co. was recently incorporated to run a line from Vincennes to Jasper, passing through Petersburg and Otwell. Smiley N. Chambers, Indianapolis, Pres.; Fred E. Chappell, Petersburg, Secy.; E. F. Cox, Worthington, Ch. Engr.

Chicago, Ill.—See "Power Plants, Gas and Electricity."

Trenton, N. J.—A charter has been filed by the People's Traction Co., incorporated with a capital of $175,000. Incorporators: Josiah K. Boughes, of Trenton; Dr. W. C. Parry, of Hainesport, N. J., and I. A. Sweigard, of Atlantic City.

Trinidad, Colo.—See "Power Plants, Gas and Electricity."

Sheffield, Ala.—The City Council has granted to I. T. Crasa, of Chattanooga, a franchise to build and operate an electric street railway in Sheffield.

Atlantic City, N. J.—The Atlantic City & Suburban Traction Co. has been incorporated with a capital of $500,000, to build a trolley line from the Boardwalk in Atlantic City to Florida Ave., Baltic Ave., Atlantic City, and over the Pleasantville turnpike to Pleasantville, with branches from the latter place to Absecon, Linwood and Somers Point, a total distance of 15 miles. The incorporators are Edw. R. Spangler, Harrisburg, Pa.; C. Taylor Leland, Philadelphia, and Albert M. Jordan, Atlantic City.

Roanoke, Va.—Press reports state that the American Asbestos Co., recently formed at Terre Haute, Ind., with a capital stock of $1,000,000, with W. A. Doak as Pres., has secured options on 4,000 acres of land in Bedford County, and expects to build an electric road from the mines to a point on the Norfolk & Western Ry., not far from Roanoke.

Lehigh, Ind. Ter.—Articles of incorporation have been filed by the Lehigh Traction Co., with a capital of $300,000. The corporation will build and operate an electric line from Atoka to Coalgate by way of Lehigh and other mining towns. Among the incorporators are Chas. Copeland, Thomas Carroll and David J. Young, the latter of Fort Smith.

San Bernardino, Cal.—A. C. Denman has applied for an electric street railway franchise on certain streets; bids for said franchise will be received Aug. 14. Legard Allen, City Clk.

Paducah, Ky.—Bids are wanted Aug. 8 for the purchase of a franchise for constructing an electric street railway, distributing electricity for lighting and furnishing power over streets known as the Rowlandtown and Union depot line. Bids are also wanted for the purchase of a franchise for constructing an electric street railway over streets known as the Broadway and La Belle park line. D. A. Yeiser, Mayor.

Lima, O.—An ordinance has been passed granting the Lima, Delphos, Van Wert & Fort Wayne Traction Co. the right to construct and operate street railway route No. 2.

Lima, Peru.—The Lima Street Ry. Co. has been incorporated at Trenton, N. J., with a capital stock of $5,000,000. The charter sets forth that the company will operate street railways in Lima and other cities in Peru. The incorporators are Chas. A. Neville, Henry W. Carter and Chas. Borch, all of Jersey City.

Knoxville, Tenn.—It is reported that a first mortgage for $1,000,000 on the property of the Knoxville, Kimberlin Heights & Sevierville Electric Ry. Co. has been filed, the amount to be used in construction.

Oklahoma, Okla. Ter.—It is stated that the So. Oklahoma City Car Line Co. has been formed to operate a 5-mile line in Oklahoma City. Capital stock, $25,000. Directors: Sam Hooker, T. J. Thompson and others.

Rhinebeck, N. Y.—It is stated that a company, of which L. B. Treadwell is Pres., has secured a franchise for an electric road from here to Rhinecliff.

Fremont, O.—It is stated that right of way has been secured for an electric line from here to Sandusky.

Traverse City, Mich.—A press report states that the Council has granted a street railway franchise to L. K. Gibbs and associates on condition that they incorporate under the general street railway act.

Chicago, Ill.—It is reported that the South Side Elevated R. R. Co. is to build 3 extensions to reach Englewood, the stock yards and the lake. The improvement is estimated to cost $10,000,000, and will involve construction of 10 miles of track.

Lancaster, Pa.—Steps have been taken for building a trolley line from a point near Strasburg, on the Lancaster & Strasburg trolley road, to a point on the Lancaster & Southern R. R. and thence to Quarryville.

Bloomsburg, Pa.—An ordinance has been passed granting the Bloomsburg & Benton Electric Ry. Co. the right of way over certain streets in this town.

Dayton, O.—The Greenville & Union City Traction Co. is reported incorporated with $10,000 capital stock, by J. E. Lowes, John E. Feight and others.

Ensley, Ala.—It is stated that J. W. Minor has been granted a franchise to build a street railway in Ensley.

Berkeley, Cal.—The Town Trus. have granted the Oakland & East Side Ry. a franchise for a railway through the town limits of Berkeley.

Hillsboro, Ore.—It is stated that an electric ry. is proposed between Hillsboro and Portland. Graydon & Son, promoters.

Elkton, Md.—It is stated that the Kent & Cecil Light, Power & Ry. Co. has been organized to construct a trolley line between Elkton and Chestertown and Tolchester Beach. E. A. Tennis, of the Tennis Cons. Co., Philadelphia, is the chief promoter.

Gulfport, Miss.—It is stated that a company is being organized by S. S. Bullis to build an electric railroad between this city and Biloxi.

Black River Falls, Wis.—Surveys are being made for a dam about 3 miles above this city to furnish power for the proposed La Crosse, Black River Falls & Neillsville Electric R. R. Estimated cost of dam and dynamos, $200,000.

Superior, Wis.—It is reported that the Duluth-Superior Traction Co. will extend the Steel Plant line to Billings Park and erect new car barns at Ogden Ave. & 4th St. Estimated cost of improvements to be made this summer in Superior, $100,000.

St. Joseph, Mo.—It is reported that the property of the St. Joseph Ry., Light, Heat & Power Co. has been sold by E. H. Harriman to Seligman & Co. and E. W. Clark & Co. W. T. Van Brunt, Pres.

Bangor, Me.—It is stated that the electric line from Bangor to Hampden is to be extended 7 miles to Winterport.

RAILROADS.

Baltimore, Md.—Press reports state that the Baltimore & Ohio R. R. will expend $25,000,000 in improvements during the next 2 years. Among the contemplated improvements are 3d and 4th tracks to be laid between Washington Junction and Cumberland, and on the Pittsburg & Connellsville line. The Fairport line will be double-tracked and the lake harbors will be enlarged. J. M. Graham, Ch. Engr., Baltimore.

Sheffield, Tenn.—Local press reports state that surveys are being made of the route of the proposed Mobile & Western Ry.

Barbourville, Ky.—The Cumberland R. R. Co., of Knox County, with $30,000 capital stock, filed articles of incorporation. The stockholders are L. R. Freeman, Fred Morck, G. H. Jackson and others, of Warren, Pa. The company will build a railroad from a point on Cumberland Valley Div. of the Louisville & Nashville, near Artemus, in Knox Co., Ky., to a point at Lupsford, Knox Co., a distance of 10 miles. The offices of the company will be at Barbourville.

Charleston, W. Va.—A charter has been issued to the Cheat River Ry. Co. for the purpose of constructing a railroad from Parsons to Rowellsburg, W. Va., thence along Cheat River to the State line, between W. Va. and Pa., to a point at or near Cheat Haven, Pa. Capital stock, $200,000. Incorporators: Wesley Mollohan, Geo. W. McClintic, Jas. H. Couch and others, of Charleston.

Cincinnati, O.—The Cincinnati & Columbus Traction Co. is stated to have completed acquiring its right of way between Cincinnati and Columbus. The distance by this route will be 119 miles.

Pittsburg, Pa.—Press reports state that the Pennsylvania R. R. Co. will soon let contracts for double-tracking part of the southwest branch, this being the line from Greensburg to Fairchance. The work involves the construction of several steel spans of 30 or 40 ft. in length, the laying of a great deal of masonry and a large amount of grading through a rough country. Estimated cost, about $300,000. W. H. Brown, Ch. Engr., Philadelphia, Pa.

Hopkinsville, Ky.—Local press reports state that the Tenn. Central R. R. (L. S. Miller, Gen. Mgr. Nashville, Tenn.), is to be extended to a junction with the Ill. Central R. R. at Hopkinsville.

Toledo, O.—The Toledo Ry. & Terminal Co. is stated to have incorporated the Toledo, Angola & Western R. R. to construct a road from Toledo to the Indiana State line.

San Antonio, Tex.—A survey is stated to have been completed for a railroad 60 miles long from San Antonio to Crowther, in Atascosa Co.

Independence, Kan.—A charter has been granted at Guthrie, Okla. Ter., to the Cherryvale, Oklahoma & Texas Ry. Co., to build 900 miles of road, from Cherryvale, Kan., through Independence and Caney, Kan., and the Cherokee, Osage and Ponca Indian reservations, to Perry, Okla., where one line will be constructed to El Paso, Tex., and another via Pawhuske, Okla., to Paris, Tex. The capital stock is $18,000,000. Independence and Perry are the principal places of business designated.

Des Moines, Ia.—Local press reports state that the Whitebreast Fuel Co. will build a road 18 miles long to afford an outlet for its products to the Milwaukee on the north, and the Great Western and Rock Island roads on the south.

Apex, N. C.—The Cape Fear & Northern R. R. will, it is stated, soon let the contract for an extension from Angier to Fayetteville. Geo. E. Lemmon, Ch. Engr.

Jefferson City, Mo.—It is stated that a charter has been granted the Arkansas, Springfield & Northwestern R. R. to build a 120-mile road from Jefferson City to Seligman, in Barry Co. Capital stock, $1,200,000. Directors: C. H. Varnon, Henry C. Solomon, C. R. Funk, and others, of Kansas City.

Denver, Col.—The Denver, Northwestern & Pacific Ry. Co. is said to have filed articles of incorporation in Denver. Capital stock, $20,000,000. D. H. Moffat, Prest.

Terre Haute, Ind.—It is reported that the Southern Indiana Ry. is to increase its stock by $1,500,000, to build branch roads in Sullivan, Green and Lawrence Counties. F. W. Ranno, Engr., M. of W.

Nashville, Tenn.—The Tennessee Central R. R., it is stated, is preparing to extend the Crawford branch to the property of the Fentress Coal & Coke Co., a length of 3 miles. G. Bottiger, Ch. Engr.

Kansas City, Mo.—It is stated that the Kansas City, Dallas & Olathe Ry. Co. has been incorporated to build 25 miles of road. Incorporators: Henry G. Pert, A. A. Potter, W. E. Winner, and others.

Montgomery, Ala.—It is reported that a survey is being made by Ausfeld & Chapman, of Montgomery, for a 10-mile railroad from Booth's Station, on the Mobile & Ohio R. R., to Autaugaville.

Canton, S. D.—The Interstate Ry. Co. is reported incorporated to build a line from Duluth, Minn., to Galveston, Tex. Capital stock, $50,000.

Akron, O.—The Summit County Ry. Co. is reported incorporated by W. W. Pope, F. E. Ream and others. Capital stock, $10,000.

Concord, N. C.—The Carolina Colony Co. has been incorporated with a capital of $5,000,000, to build a railway from Concord, its principal place of business, to Fayetteville.

Oakland, Cal.—The East Side R. R. Co., M. J. Keller, Pres., has accepted the terms of the franchise which permit it to construct a road from Point Richmond to Emeryville.

Pittsburg, Pa.—It is stated that the Pittsburg Terminal R. R. & Coal Co., with a capitalization of $14,000,000, is preparing to build a mammoth railroad clearing yard.

New York, N. Y.—The Rapid Transit Subway Construction Co., now building the Manhattan-Bronx rapid transit subway, was, on July 24, awarded the contract for the construction of a tunnel and underground route to Brooklyn for $2,000,000. Three bids for the work, which it was estimated would cost $8,000,000, were received July 21 by the Rapid Transit R. R. Comn., as follows: Rapid Transit Sub. Con. Co., two bids; one, $3,000,000; the other, $2,000,000, the former bid being accompanied by a letter offering to construct an additional subway in the Manhattan-Bronx route for $100,000 provided that bid was accepted, the additional subway being located under Broadway, New York, between 42d St. and 14th St., and likely to cost, according to the estimate of the chief engr. of the Comn., Gen. Wm. Barclay Parsons, $3,600,000. The third bid was submitted by John L. Wells, as counsel for the Brooklyn Rapid Transit Co., and agreed to construct the Manhattan-Brooklyn route for $7,000,000. All three bids are exclusive of terminal and real estate, and estimated the cost of equipment of the road to be $2,000,000. The first two bids provide for a single ride without change of cars for a maximum fare of 5 cents from the Brooklyn terminus of the road to 59th St., New York, while the third offered a 5-cent ride from the outlying termini of a large number of the surface roads in Brooklyn to the New York terminus of the road at City Hall, and included the offer to construct an additional tunnel in Brooklyn to facilitate the movement of through trains. The contract provides that the contractor shall operate the road for a period of 35 years, with a right to a renewal for a term of 25 years. An annual rental is to be paid amounting to the interest paid by the city on its bonds for construction and 1 per cent. on the cost of construction. The work is to be started in 60 days and finished in 3 years, with a possible extension of 1 year in the East River work.

A resolution was adopted directing the Chief Engineer to draw plans for a direct tunnel route from City Hall, New York, to Boro. Hall, Brooklyn.

PUBLIC BUILDINGS.

West Seneca, N. Y.—Local press reports state that a brick building, to cost when fully equipped $125,000, is to be erected on site recently purchased on Ridge road, opposite Ingram Ave., in West Seneca, as an accident hospital in connection with the Lackawanna Steel Co.'s plant at Stony Point.

Racine, Wis.—Plans of A. C. Eschweiler, of Milwaukee, are stated to have been selected for the $25,000 church edifice to be built by St. Rose Church congregation.

Paterson, N. J.—Contracts for repairing the city hall have been awarded as follows: For plastering and marble work, to David Henry Bldg. Co., of Paterson, at $24,783; for carpentering work, to P. S. Van Kirk Co., Paterson, at $32,976; for electrical work, to the Northern Engineering Co., at $5,192.

St. Louis, Mo.—The Illinois Comrs. to the Louisiana Purchase Exposition are stated to have decided to erect at the World's Fair a $75,000 building to be constructed of wood and staff, 100x60 ft., with a veranda 20 ft. wide on each side. Competitive plans will be submitted for the building. Jas. M. White, of Champaign, Ill., is Consulting Archt.; Senator H. M. Dunlap, Savoy; Hon. John J. Brown, Vandalia, Pres., and Hon. James H. Farrel, Chicago, are among the Comrs.

Lewiston, Mont.—Bids are wanted July 31 by the Bd. of Co. Comrs. for building a pest house on the county poor farm. C. M. Kelly, Co. Clk.

Canton, O.—Bids are wanted Aug. 1 for erecting a church for St. Joseph's congregation. Address Jos. Dick, 1413 W. Tusc St.

Mitchell, S. D.—W. A. Dow, of Sioux Falls, has submitted to the City Council plans for a city hall, estimated to cost $20,000.

Washington, D. C.—The contract for building the engine house of Congress Heights has been awarded to Jas. M. Dunn, Washington, for $19,969.

Junction, Utah.—Bids are wanted July 29 for the erection of a court house for Piute Co. Horace Morrill, Co. Clk. R. C. Watkins, Archt., Provo City, Utah.

New York, N. Y.—Bids are wanted Aug. 1 for alterations and repairs to Bellevue Hospital and Bellevue Emergency Hospital. John W. Brannan, Pres. Bd. of Trustees, Bellevue and Allied Hospitals.

Marshalltown, Ia.—The State Bd. of Control, Des Moines, will receive bids July 31 for improvements at the Soldiers' Home at Marshalltown, estimated to cost $70,000.

NEW INDUSTRIAL PLANTS.

The Emmert Mfg. Co., Waynesboro, Pa., expects to be in the market early in the fall for machinery, as it intends to build an additional shop.

The Callery Junction Brick & Tile Co., Callery, Pa., intends to erect a plant having a daily capacity of 20,000 brick.

The Powers Mfg. Co., Powersville, Iowa, is erecting a 2-story and basement, 32x100-ft. factory at Waterloo, Iowa, and expects to install a gasoline engine of about 10 H.-P.

The McClary Mfg. Co., London, Ont., is having plans prepared for a 198x220-ft. foundry; 2-story, 80x250-ft. mounting shops; 2-story polishing and fitting shop; power house and storage buildings. It is intended to operate by electric power and use compressed air for hoists, etc.

The Browansville, Tenn., Cotton Oil Co. is erecting a 40-ton oil mill. The power will be furnished by two 60x16-in. boilers and a 16x36-in Corliss engine.

The Louisiana Central Lumber Co., Clarks, La., contemplates erecting a double band saw-mill with a planing mill of about ten machines. Seven 66x72-in. boilers, a 300 and a 500-H.-P. engine, five brick dry kilns, machine shops, etc., will be required, to manufacture about 100,000 ft. of lumber daily. Contracts for planing mill machinery and boilers have been let.

The Apalache Mills, Greer Depot, S. C., will erect a 2-story, 104x200-ft. mill building and a 130x200-ft. loom shed. Water power will be used, with an immediate development of 500 H.-P. and a subsequent development of the same amount. There will be installed 17,000 spindles and 400 looms. Lewis W. Parker, Pres. & Treas.

The Wyoming Spinning Co., Norristown, Pa., is erecting a new factory.

The Garland Nut & Rivet Co., Frick Bldg., Pittsburg, Pa., capital stock $200,000, has taken over the business of the rivet department of the Garland Chain Co. and the Dunham Nut Co., Unionville, Conn., and will make hot and cold rivets and hot and cold pressed nuts. A 690x80-ft. brick factory building, to have a daily capacity of 20 tons, will be erected at West Pittsburg. The power plant will have a capacity of 250 H.-P. and the entire plant will be run by electricity. John W. Garland, Pres.; Robt. Garland, Treas.; Alfred Sang, Gen. Mgr.

Plans and specifications can be seen at the office of Joseph H. Wallace, Temple Court Bldg., New York, for the superstructure of a mill for the Kalamazoo, Mich., Paper Co., on which bids are wanted.

P. H. MaGirl, Bloomington, Ill., contemplates the erection of a foundry in the near future, but plans have not been adopted.

The Jasper, Tex., Brick Co. has been organized with a capital of $20,000, and proposes to install a plant with a daily capacity of 60,000. L. P. Scarborough, Secy.

The Horton Mfg. Co., Painesville, O., makers of brick machinery, expect soon to erect a 350x60 and a 50x100-ft. building and install a 100-H.-P. Corliss engine.

BUSINESS NOTES.

Jones & Laughlins, Pittsburg, Pa., have ordered from the Westinghouse Electric & Mfg. Co. one 800-Kw. direct-current generator, two 150-Kw. motor-driven two-phase alternators and two 125-light motor-driven arc generators.

The Allis-Chalmers Co., Chicago, reports the following among its sales during June, the engines being 1890 frame Reynolds Corliss unless otherwise stated: W. F. Stewart Co., Flint, Mich., 18x36-in.; Russell, Burdsall & Ward Bolt & Nut Co., Port Chester, N. Y., 22x48-in.; Brown, Cary & Woodruff Co., Salt Lake City, Utah, 12x36-in.; Tyee Copper Co., Ladysmith, Vancouver Is., 14x36-in. girder frame; Kioto, Japan, Traction Co., 16 and 32x36-in. cross-compound direct-coupled; P. A. Peterson, Rockford, Ill., 10x30-in.; Park City, Utah, Sampling Mills, 16x36-in.; Hudson River Lumber Co., Kansas City, Mo., 20x42-in.; International Paper Co., New York, 16x42 in.; Virginia-Carolina Chemical Co., Richmond, Va., 16x42 and 20x42-in. girder frame; Janesville, Wis., Cement Post Co., 14x36-in. girder frame; Geo. T. Houston, Chicago, 28x48-in.; Twin City Rapid Transit Co., Minneapolis, Minn., 46 and 94x60-in. vertical cross-compound direct-coupled (third order); West Allis, Wis., Malleable Iron & Chain Belt Co., 12x30-in. girder frame; John Q. Gant, Elon College, N. C., 18x48-in.; London, Eng., United Tramways, 26 and 54x48-in. vertical cross-compound direct-coupled (second order); Pennsylvania Railroad Co., Riedler air compressor with 15 and 24x36-in. air cylinders, driven by cross-compound non-condensing Corliss engine with 14 and 24x36-in. steam cylinder; Kennedy M. & M. Co., California, direct-acting double-drum hoisting engine with 10x7-ft. drums, driven by a 28x60-in. duplex Corliss engine.

The United Railways & Electric Co., Baltimore, Md., is installing a 350-H.-P. tandem compound engine, built by the Ball Engine Co., Erie, Pa.

The Thomson Meter Co., Brooklyn, N. Y., has received a contract for 1,500 ⅝-in. Lambert water meters and couplings from the City of San Juan, P. R.

G. M. Gest, 277 Broadway, New York, has received through his Cincinnati office a contract for 100,000 duct-feet of underground work of the Bell Telephone Co., of Cincinnati.

The Edison Electric Illuminating Co., Boston, has contracted with the Green Fuel Economizer Co. for an installation of an economizer in their Atlantic Avenue power station.

The Duquesne Fireproofing Co. is building a new plant at West Winfield, Butler Co., Pa., to be equipped with the latest machinery for the manufacture of sewer pipe, brick and fireproofing. The building will be 200x150 ft. Most of the machinery has been purchased. F. W. McKee, Pres.; E. J. Fronheim, Vice-Pres.; Joseph Fronheim, Secy.; W. C. Linn, Treas.; George H. Albertson, Gen. Mgr.

The Phoenix Iron Works Co., Meadville, Pa., reports the following among its recent orders: Farmers' Deposit National Bank, Pittsburg, three 240-H.-P. tandem compound engines and a 120-H.-P. simple engine; Grafton, W. Va., Gas & Electric Light Co., a 200-H.-P. tandem compound engine; Penn Iron & Coal Co., Canal Dover, O., two 320-H.-P. tandem compound engines; Mt. Pleasant Hotel Co., Fabyan, N. H., three 480-H.-P. simple engines; R. H. Macy & Co., New York, two 320-H.-P. tandem compound engines; H. C. Hallenbeck, New York, two 240-H.-P. tandem compound engines and an 80-H.-P. simple engine; Maritime Building, New York, three 120-H.-P. simple engines; Dunlap Building, Philadelphia, two simple engines; Cafe Martin, New York, two simple engines; Paulinskill Consolidated Power & Ice Co., Columbia, N. J., a 600-H.-P. cross-compound engine; Lehigh Power Co., Easton, Pa., a 600-H.-P. cross-compound engine; Chas. L. Seeger, San Vincente, Mex., a simple engine; Heyden Chemical Co., Garfield, N. J., a 125-H.-P. compound engine; W. J. Moxley Building, Chicago, two 200-H.-P. compound engines, and a 65-H.-P. simple engine; United Electric, Gas & Power Co., Santa Barbara, Cal., a 175-H.-P. compound engine.

The Sprague Electric Co. reports that in addition to foreign orders and contracts for small apparatus, it has recently made the following sales: Atlas Portland Cement Co., Hannibal, Mo., seven 35-H.-P. motors and eight 15-H.-P. motors; Atlas Portland Cement Co., Northampton, Pa., 30-H.-P. motor and two 35-H.-P. motors; E. W. Bliss, New York, fifteen 10-H.-P. motors, seventeen 25-H.-P. motors and one 50-H.-P. motor; Lehigh Portland Cement Co., Wellston, O., one 300-Kw. belted generator, one 230-H.-P. motor and six smaller motors aggregating 100 H.-P.; Emery Bird Thayer Dry Goods Co., Kansas City, three split-pole engine-type generators, 60 Kw., 100 Kw. and 350 Kw., respectively; Mergenthaler Linotype Co., Brooklyn, one 150-Kw. split-pole engine-type generator; Government Printing Office, Washington, D. C., contract for ventilating plant, consisting of direct-connected American blowers and the following motors: one 5-H.-P. motor and one 10-H.-P. motor, two 15-H.-P. motors and eight 20-H.-P. motors; Hatzel & Buehler, New York, one 125-H.-P. motor for the New York Herald; the Alliance Press, New York, nine motors for printing presses; Lackawanna Steel Co., West Seneca, N. Y., one 3-ton trolley hoist; the John Simmons Co., New York City, one 50-Kw. belted generator and two 20 and 25-H.-P. motors; Shoreham Hotel, Washington, D. C., three split-pole engine-type generators to develop 50, 75 and 100-Kw. respectively; Baltic, Conn., Mills Co., one 75-Kw. split-pole belted-type generator; Gorham Mfg. Co., Providence, R. I., one 40 H.-P. motor; Utica Steam and Mohawk Valley Cotton Mills, Utica, N. Y., two 100-Kw. split-pole belted generators; Duluth, Minn., Printing & Pub. Co., one 25-H.-P. motor; New York Life Insurance Co., New York City, two 50-Kw. split pole belted generators; James Wilson, Pittsfield, Mass., one 150-Kw. belted generator; United Coke & Gas Co., Sharon, Pa., one 50-H.-P. motor and one 15-H.-P. motor; Pennsylvania Steel Co., Steelton, Pa., ten 5-ton trolley hoists; Sigourney Tool Co., Hartford, Conn., one 75-Kw. split-pole engine-type generator; Lindell Hotel Co., St. Louis, one 60-Kw. and one 75-Kw. split-pole belted-type generator; American Can Co., New York, one 75-Kw. engine-type generator and one 35-Kw. belted generator; Lewis Institute, Chicago, one 75-Kw. split-pole engine-type generator; George A. Fuller Co., New York, four 25-H.-P. motors and one 10-H.-P. motor; Hibbard-Rodman-Ely Safe Co., Plainfield, N. J., two 25-H.-P. motors; Goes Lithograph Co., Chicago, 20 motors, various sizes; Tucker Elec. Construction Co., for the National Meter Co., Brooklyn, N. Y., one 75-Kw. split-pole engine-type generator.

The West Virginia Reform School at Fetterman, W. Va., is installing an electric plant. The engine will be furnished by the Ball Engine Co., Erie, Pa., and the generator by the Westinghouse Elec. & Mfg Co.

The Field Force Pump Co., Lockport, N. Y., reports the following among its recent sales of Carter pressure water filters; Troy & Cohoes Shirt Co., Cohoes, N. Y., a 40-in. filter, having a capacity of about 50,000 gal. daily; F. D. Killian, Washington, D. C.; G. E. Crawford, Bridgeport, Conn.; Chas. B. Scott, Scranton, Pa., and Slayton & Partridge, Wheeling, W. Va.

The Oliver Schlemmer Co., Cincinnati, O., engineers and contractors for steam and hot-water heating, power-pipe fitting, plumbing and drainage, have succeeded to the business of Oliver Schlemmer, and are prepared to do work on a larger scale than before. The officers of the company are: Pres., Oliver Schlemmer; Vice-Pres. & Mgr., Clifford T. Schlemmer; Secy. & Treas., Oliver H. Schlemmer.

W. H. Wagner Sons, Freeport, Ill., are installing an electric plant consisting of Crocker-Wheeler generator direct connected to an engine built by the Ball Engine Co., Erie, Pa.

Geo. M. Brill, Marquette Bldg., Chicago, has been retained as consulting engineer for the plant of the Victor Chemical Works, Chicago Heights.

Westinghouse, Church, Kerr & Co. announce the removal of their Pittsburg office from its former location on the first floor of the Westinghouse Building to more commodious quarters on the eighth floor of the same building. This change is the direct outcome of largely increased business in this district, and is accompanied by the acquirement of a commodious reception room devoted exclusively to the convenience of visitors.

Sanger Bros., Waco, Tex., will install an electric plant in their dry goods house, the engines being furnished by the Ball Engine Co., Erie, Pa.

The pipes in the plant of the Tesla Laboratory, Warden Clyffe, N. Y., were recently covered by the H. W. Johns-Manville Co. Mr. Tesla writes: "I have watched this work with interest, and am well satisfied with the manner in which it has been done." The covering used in this instance is the asbestos-sponge felted sectional pipe covering, constructed of fibers of asbestos and a small quantity of granulated sponge, thus combining the properties of asbestos with the lightness and porosity of sponge.

The Philadelphia Pneumatic Tool Co. has concluded arrangements for representation in South Africa, with headquarters at Johannesburg. This agency will be in charge of Gen. Samuel Pearson, late of the Boer forces. Gen. Pearson has been in the United States for some months in the interests of his Government, in the attempt to have the mule shipments from Port Chalmette stopped. Now that peace has been declared he will return to his former business in the machinery lines and will handle the accounts of the Philadelphia Pneumatic Tool Co. and others.

TABLE OF LEADING ARTICLES.

American Shop Practice in Bridge Construction. 97
The Mechanical and Electrical Equipment of the Pittsburg & Lake Erie Railroad Terminal, Pittsburg.—I. (Illustrated) 98
Test of a De Laval Steam Turbine Using Superheated Steam 100
The Second Division of the New York Rapid Transit Railroad.—III. (Illustrated) 102
The Loss of Capacity of the Vyrnwy Aqueduct 103
Concrete Sewer Construction at the Chicago Clearing Yards 104
The Erection of the Uganda Railway Viaducts. (Illustrated) 105
Test of a Concrete Slab Reinforced with Expanded Metal. (Illustrated) 106
New Repair Shops of the Rhode Island Suburban Railway. (Illustrated) 107
Plumbing in the Carnegie Residence, New York. (Illustrated) 108
The Economic Need of Technical Education 111

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

American Shop Practice in Bridge Construction.

In January of the current year Mr. Henry Bridges Molesworth presented a paper before the Institute of Civil Engineers entitled "American Workshop Methods in Steel Construction," which possesses much interest for American engineers and manufacturers, and scarcely less for British bridge builders and engineers, as is evidenced by the tone of some of the discussions of it by members of the Institution. Mr. Molesworth's professional practice has brought him to this country in connection with a number of bridge structures which have been built for British colonies by the American Bridge Company at their Pencoyd shops, and he has been prompted by his observations to give to his professional brethren at home the reasons why American bridge builders have been able to underbid British constructors in modern steel bridgework. In passing it may be stated that our friends across the water have on various occasions assigned reasons for this state of things quite different from those set forth by Mr. Molesworth. At the very outset of his paper he states his judgment that "first-class American bridgework is fully equal, if not superior, to the best English work in design, material, workmanship and finish." Consequently there must be some more substantial basis for the underbidding of British constructors by those in America than that the work of the latter is of indifferent quality.

After giving a comprehensive and clear statement of some of the workshop methods and other features of the work executed at the Pencoyd shops, Mr. Molesworth proceeds to make comparison in a number of respects between the business of bridge construction in America and in Great Britain. Undoubtedly the unwise features of trades unions rules and influences are much more marked in Great Britain than in this country, to the decided financial disadvantage of the laborer himself in such a way as to greatly reduce his efficiency in the mechanical operations of the shop. In this country we certainly have no lack of active labor organizations nor do they avoid all measures that are unwise, but the American mechanic, in spite of all this, is a vastly more effective operator than the same type of man in Great Britain. Notwithstanding his pay may be two or three times that of the English mechanic he conducts his operations so much more effectively as to turn out four or five times as much work, making his services correspondingly more valuable. Doubtless the ability of the American bridge builder to undersell his British competitor in the colonial market of the latter is due largely to the greater efficiency of the American mechanic, as has many times been observed, but there is much more than that in the question, as Mr. Molesworth indicates.

He remarks most pointedly upon the readiness and perhaps even indifference with which the American shop owner or manager practically relegates to the scrap-heap, machinery in actual use, when improved machinery and tools may be made to produce a greater output at smaller cost. This is a feature of American shop and mill management which has not escaped the notice of many astute observers, and yet the wisdom of such a policy has not been promptly recognized even in some large American works. By far the most successful shops and mills in this country are those in which the most frequent changes of machines and tools have been made in the development of greater rates of output at reduced unit costs, whatever other influences may have aided in giving the American bridge constructor his present advantageous position. Mr. Molesworth makes this among his most effective points, although a number of his fellow members of the Institution could not apparently endorse his views.

Aside from the labor feature of the question, one of the discussers of the paper, Mr. H. F. Donaldson, put himself close to the kernel of the question when he said that "he read into the paper three main points, standardization, specialization and organization." He could scarcely have phrased the matter in a better way, for those three features have characterized American bridge practice most markedly ever since the building of bridges began in this country. Although there is, and always has been, reasonable latitude in design both among engineers and in the shops to meet the varying requirements of locality and competent individualism in the designer, there has been the constant standardizing motive through it all. This has not degenerated on the one hand into unprogressive routine, nor on the other to erratic or fanciful individual excess. Avoiding those extremes there has been a steady advance in excellence, with which standardizing of types, details and methods or processes, has been constantly introduced.

Again, the most scrupulous study has been given in this country to the organization of the office force and of the shop, also observed by Mr. Molesworth. This efficient organization enables the maximum of results to follow from the standardization which has been such a marked feature of American bridge work. Under these conditions there is no unnecessary loss in useless variety of operations in the shop. Every engineer familiar with shop processes is aware of the tremendous advantage of duplication resulting from standardizing in every possible branch of shop work, and this advantage is manifolded by shop organization which turns every handling of a piece into a long and direct step toward the shipping platform. Equal efficiency has been carried into the office force, including the computing and drafting rooms.

It is due to all these features of the American bridge constructing work that the output from the bridge shop per man in this country is from four to six times that in Great Britain, and that the fixed charges per ton of work in Great Britain may be even ten times as much as in the United States. In all probability ultra conservatism in Great Britain has much to do with these relative results. In this country expedition and economy have been absolutely imperative, sometimes it must be admitted to the impairment of the highest degree of excellence. This latter observation, however, has no application at the present time to any of the first-class American bridge work. The advantage which the American builder holds in the world markets is due both to the effective character of the American mechanic and to the advanced degree of engineering excellence in design and shop execution, both on the part of the engineer and the shop manager; both have had their parts to play and they have played them well. While in special instances there has been now and then a little friction, on the whole the civil engineer has striven for the highest degree of excellence in design and construction in such a way that the shop manager has had abundant opportunity to project into the final results, all the excellence which can follow from the most advanced shop organization and management.

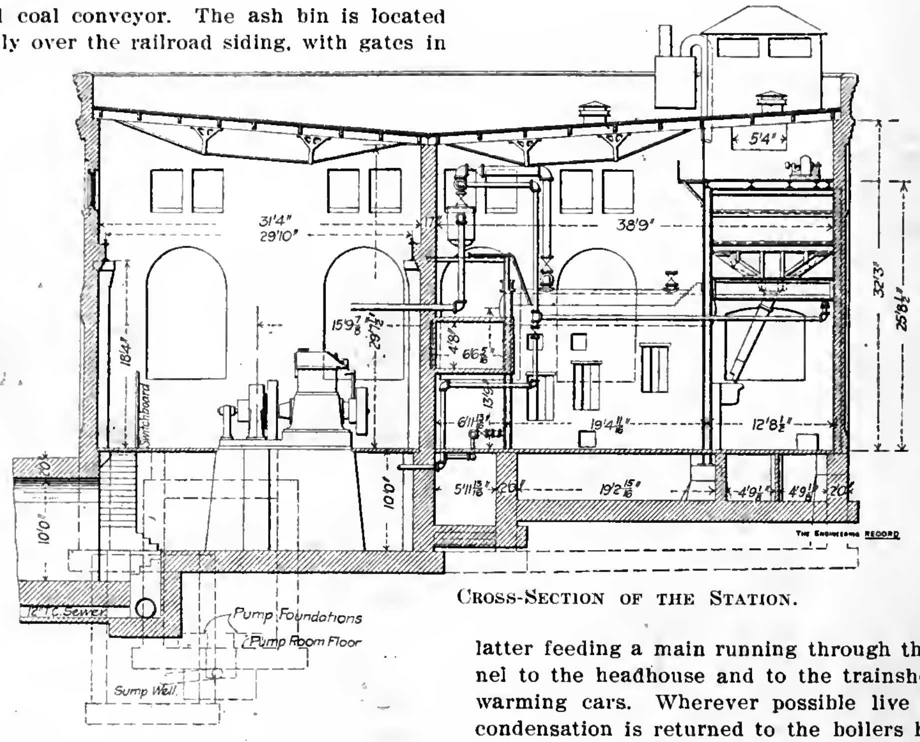
The Diverse Views held by courts of final jurisdiction in different States concerning the same subjects are exemplified by recent decisions of the Supreme Courts of Vermont and Ohio concerning the right of a town or water company to supply river water for manufacturing purposes, to the detriment of lower riparian power privileges. In the Vermont case, 50 Atl. Rep. 1,055, the Barre Water Company was enjoined from supplying water to granite-polishing works on the ground that such a supply diminished the flow to which lower riparian owners were entitled. The company's charter allowed it to take the water for the town and its inhabitants "for the extinguishment of fires, and for domestic, sanitary and other purposes." The court rules that "other purposes" should be construed to mean other like purposes, and that the sale of water for manufacturing uses does not come under this head. The second case, 63 N. E. Rep. 600, was brought against the City of Canton, Ohio, by a lower riparian owner, who contended that the city had no right to furnish water for manufacturing purposes when it thereby impaired his power privilege. The court decides that the city has the right to supply all reasonable manufacturing needs in addition to domestic requirements, within the municipal limits. The city is held to be an individual entity, endowed with all the rights and liabilities of a riparian owner. One of these rights is the reasonable use of water, and the court holds that the use of water for any legitimate industrial purpose is legally reasonable and subject only to one restriction. This is the equitable division of the water, other than that for domestic uses, between all riparian owners during periods of a scanty supply. This radical departure from the interpretation of the law of riparian rights made by the Vermont court is no greater than was the deviation from its view of "other purposes" which is recorded as happening years ago in Rhode Island. An eminent Senator was called to account for the unauthorized existence of a State bank in which he was interested that had been refused a charter by the Legislature. He admitted that the bank was openly doing a thriving business in Providence, but explained that it was working under the charter of the First Free Will Baptist Society of Foster Center, which was chartered "for the worship of God and other purposes." He certainly considered running a bank well within the scope of "other purposes," a view that the investigators were constrained to consider warranted by the facts.

The Mechanical and Electrical Equipment of the Pittsburg & Lake Erie Railroad Terminal, Pittsburg.—I.

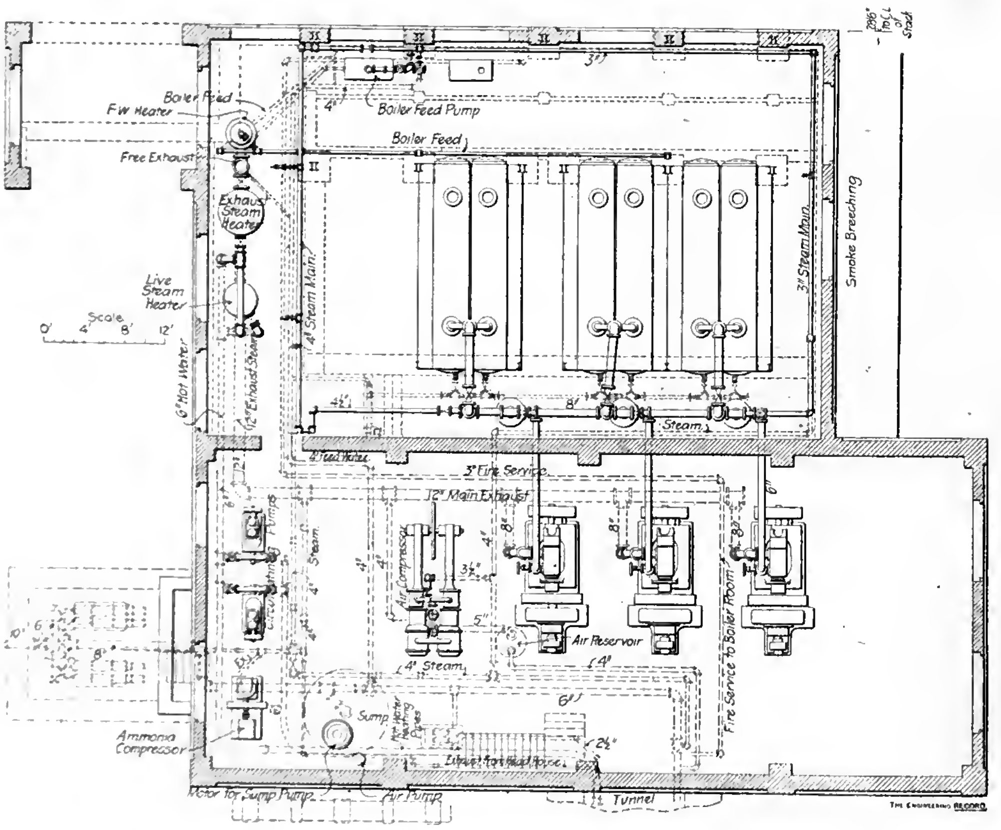
The Pittsburg & Lake Erie Railroad Company has been operated for about a year from a reconstructed terminal at Pittsburg, which includes a new seven-story station building or headhouse, a steel trainshed 500 feet long connected with the headhouse by a concourse 55 feet wide, freight sheds and an express building. The basement of the headhouse is largely taken up with apparatus for warming and ventilating the building, elevator machinery and other auxiliaries to meet the requirements of an up-to-date terminal. The power plant is installed in a separate detached building, and is connected to the headhouse by a tunnel, which also forms a passageway for all service wires and pipes. The principal equipment consists of three boilers and stokers, a total of 750 horse-power with space provided for one-third increase, a coal and ash-handling plant, three electric generating sets with room for a fourth, air compressors, a water distilling and refrigerating plant and several pumping plants for general drainage, for fire protection and for hot and cold-water supply.

The power house is a well lighted and well ventilated brick building with steel truss roof. The principal apparatus and piping is shown in the accompanying plan and sectional elevation. The boilers are of the water-tube type made by the Aultman & Taylor Machinery Company. They are designed for a working pressure of 150 pounds per square inch and are equipped with Roney mechanical stokers and smokeless furnaces adapted to burn all kinds of hard or soft coals. Coal and ash handling machinery of the bucket and chain type has been installed by Messrs. Heyl & Patterson, of Pittsburg. Coal is dropped from hopper bottom cars on a railroad siding into a chute, which carries it by gravity to an electrically driven elevator operated by a 7½-horse-power motor. By the elevator the coal is raised to a horizontal conveyor, also driven by a 7½-horse-power motor, which distributes the coal into an overhead masonry storage bin. From this it is drawn by gravity through steel spouts to the stoker hoppers. The apparatus has a capacity of 35 tons per hour, and the bin will hold 100 tons. Ashes are drawn from the furnace pits upon the boiler room floor and wheeled to an opening in the floor, where they are dumped into the boot of the same elevator which is used to elevate the coal. By means of a switch damper in the discharge end of the elevator the ashes are delivered into a masonry ash storage bin, instead of being discharged upon the horizontal coal conveyor. The ash bin is located directly over the railroad siding, with gates in the bottom to control the flow of ashes to the car. Draft is furnished by means of a self-supporting steel stack 135 feet high, lined with red brick its entire height, and 6 feet in inside diameter.

Steam is conveyed from the boilers to the engines and pumps through main piping supplied with separators, as shown, the separators being high enough so that the entrained water is returned to the boilers by gravity. Long turn bends of iron pipe were used for drops from the main header to the engines, and mention may be made here of the fact that no expansion joints are employed in any of the piping in the plant. The miscellaneous service requiring live steam and the auxiliary apparatus is supplied by a system of auxiliary piping having its origin in both ends of the main header, but otherwise independent of it. The auxiliary system comprises two loops, one in the boiler room and the other in the engine room, the latter feeding a main running through the tunnel to the headhouse and to the trainshed for warming cars. Wherever possible live steam condensation is returned to the boilers by the Holly gravity return system.



Cross-Section of the Station.



Power Plant of the Pittsburg & Lake Erie Terminal, Pittsburg.

The main exhaust piping receives the exhaust steam from all engines and pumps, and is utilized for heating water for warming the buildings and for heating the boiler feed. The exhaust heaters are provided with by-pass piping around them by which the surplus exhaust steam can pass through an exhaust muffler above the roof of the power house. The feed water heater is a 700-horse-power Goubert closed type heater. Although located on the bank of the Monongahela River, a steam condenser was found inadvisable, as the small saving possible by the use of a vacuum during the comparatively short periods when there would be surplus exhaust steam not required for heating, did not warrant the investment.

Three 14 and 24x14-inch Westinghouse single acting compound automatic engines are installed in the engine room, having an aggregate capacity of 600 nominal indicated horse-power, each directly connected with a 120-kilowatt Westinghouse engine-type generator. The engines are furnished with wrought-iron operating platforms with connecting galleries and pipe hand railings. A hand power traveling crane, having a lifting capacity of 20,000 pounds spans the engine room and travels its full length.

Direct current at 110 volts is used for arc and incandescent lighting, for the elevators and dumb waiters, and for motors to operate the coal and ash handling machinery, sump pump and ventilating fans, as follows:

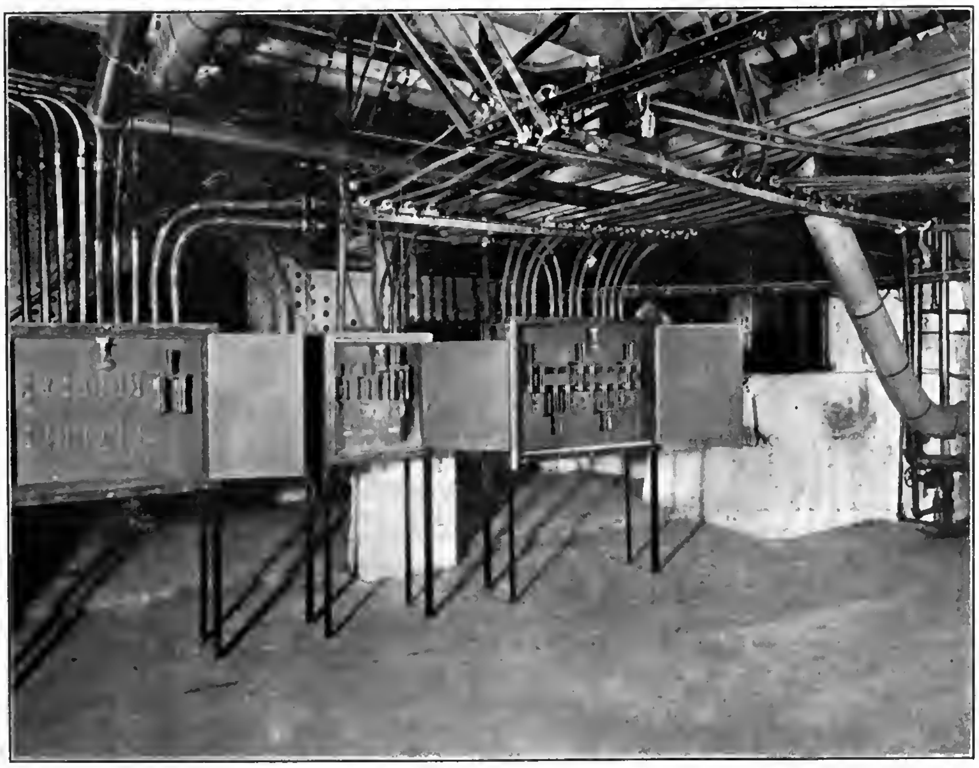
2,700 incandescent lights	159.5 kilowatts
71 arc lamps	43. "
5 elevators and dumb waiters	60.4 "
10 motors	53. "

Ordinarily two generators supply the current, the third being spare. The main switchboard is of white marble, the generator panels are located at one end of the board, the distributing panels at the other and a load panel in the center. Thirteen feeder circuits are carried from the board to distributing centers, located conveniently and with regard to the best general distribution, in different parts of the premises. Steel cabinets containing slate panels, with the necessary switches and fuses for local control of lights, are provided at distributing centers. Similar cabinets containing cutout panels are located where required. All cabinets are slate lined and in appropriate places are furnished with plate glass doors. Switches and fuses throughout the work are placed on the front of the boards, while all wires, bus bars and connections are on the back. Rubber covered lead sheathed cables are used for connecting the generators with the switchboard; feeder cables between the board and distributing centers have weather proof insulation; sub-feeder cables and branch wiring to lights are heavy rubber covered with double braid insulation installed in unlined steel conduit, concealed in the floors, walls and ceilings. The lighting system includes an illuminated sign: "P & L E R R" in letters 8 feet high, above the roof of the terminal station. The trainshed has an arc lamp for every 50 feet throughout the entire length of each platform.

Compressed air is used for cleaning coaches, for testing and charging train brakes and train signals prior to a train's departure and for cleaning the electric generators and motors. The supply is furnished by a horizontal duplex steam driven Laidlaw-Dunn-Gordon air compressor having a capacity to compress 500 cubic feet of free air per minute to 100 pounds pressure, a 9½-inch Westinghouse locomotive air pump being installed as an auxiliary for use in case of repairs to the larger machine, or at times when reqnirements for compressed air are small. Air is distributed through pipe mains equipped with large receivers or reservoirs, and the compressors are provided with automatic governing devices for maintaining a constant pressure on the system.

The water pumping apparatus for the station includes in addition to the domestic hot and cold water supply, a pump for the general supply of water, a pump for the fire service and a centrifugal motor-driven pump for the disposal of drainage. The general supply and fire pumps are located side by side in a pump pit outside the engine room, the water being led to the pit from a well driven between the power house and the river. The general water supply pump is a compound duplex steam pump, and water for all purposes, except fire protection, but including boiler feeding, domestic supply in all buildings for street sprinkling and for locomotive supply tanks can be supplied from it. It is cross-connected with the fire pump, so that either may reinforce or temporarily do the work of the other during repairs. By other pipe connections and controlling valves either pump or both can work in connection with the drainage pump during emergencies or floods, the three having a total capacity of 2,000 gallons per minute.

TUNNEL CONNECTING POWER STATION AND HEADHOUSE.



PANEL BOARDS IN THE HEADHOUSE BASEMENT.

The fire pump is a steam driven duplex underwriters' pump with a capacity of 500 gallons per minute at a pressure of 100 pounds. Mains from this pump connect with risers in the buildings and to hydrants throughout the yards. Two risers are in place in the headhouse, with hose connections on each floor and at the roof, a total of 18 outlets, connected with hose ready for instant use. The pump is continually under steam, and by means of a Ford governor, automatically maintains a constant pressure in the fire system.

The need of special provision for drainage arose from the fact that at times of flood the river rises more than 30 feet above mean low water line, making it necessary to provide means to handle water which might find its way through the waterproofing of the floor and side walls of the basements during high-water periods. A large sump well was built below the basement of the power house to receive all drainage from rooms below the high-water line. A vertical centrifugal pump, made by the Baldwinsville Centrifugal Pump Works, located in the bottom of this sump, but having its shaft extended through basement to engine room, is direct coupled to a special vertical Westinghouse motor of 20 horse-power capacity. The pump is designed to handle 1,000 gallons per minute and is automatically started and stopped by the rise and fall of a float connected to a Cutler-Hammer starter. If the water to be handled exceeds the capacity of the pump, the float continnes to rise, making an electric connection to a high-water alarm. Under these conditions the fire and general water supply pumps can be put into action, as already stated.

For the domestic hot and cold water supply separate pipe systems deliver hot and cold water to wash bowls, toilet rooms and baths. The system for hot water is connected to a closed National heater containing a live-steam coil, the desired temperature being maintained by thermostatic control of the steam supply. The hot-water is circulated by gravity through several loops of distributing piping, which leave and return to the heater. The supply for these systems is taken from the general water supply pipe, and a constant pressure is maintained in the distributing system by a small duplex steam pump, controlled by a Ford governor.

The drinking water system comprises a filtering, distilling and a cooling apparatus, to render the water pure and palatable and afterwards to prevent its becoming contaminated by contact with impurities in the atmosphere. To accomplish this all apparatus is air tight. The water to be treated passes through a pressure quartz filter, which removes matters held in suspension, then to a Jewell water still where the water is evaporated by a submerged steam coil and to a surface condenser forming part of the still, which has a capacity of 25 gallons per hour. The distillate is piped to a closed storage tank in the basement containing submerged ammonia refrigerating coils by which the water is cooled to the desired temperature. A small steam pump circulates the water through highly insulated loops of piping to fountains in offices, corridors and waiting rooms, and it is intended to carry it to the trainshed for filling drinking tanks in all outgoing trains. The refrigerating plant, consisting of a Westinghouse ammonia compressor direct coupled to a slow-speed vertical engine, together with an atmospheric condenser and auxiliaries, is located in the power house.

The elevator equipment of the building is electric, and comprises two passenger elevators, one freight elevator and two dumb waiters. The passenger elevators are designed to carry a live load of 2,500 pounds each, at a speed of 250 feet per minute, the freight elevator a live load of 5,000 pounds and the dumb waiters a live load of 300 pounds each. The freight and passenger cars operate between the ground and upper floors. The dumb waiters for restaurant and kitchen use operate between the basement, where all supplies are received, to the kitchen, located on the sixth floor. The elevator machinery was manufactured by the Sprague Elevator Company and the freight and passenger cars have electric lever control. An electric device connects the hoistway gates with the machines and prevents the starting of a car unless all gates in its hoistway are closed and locked. The dumb waiters are operated by a full automatic push button control, by which an attendant at any floor may send a car to any other floor by pushing a button. The hoistway doors to these shafts are also electrically connected with the machines in a similar manner to the large elevators.

As already stated, the terminal is warmed by hot water. The system is a closed circulating system, with two heaters for warming the water, one to utilize exhaust steam, and the other for live steam when the exhaust steam is insufficient, and with centrifugal pumps to obtain a positive circulation. The pumps are driven by vertical steam engines and are in duplicate to prevent an interruption of the system. The heaters and pumps are located in the power house and the temperature is regulated there to meet atmospheric changes during the day or season without the necessity of turning on or off radiators in any of the rooms warmed. The water is distributed through both direct and indirect radiators in the headhouse, but it is intended to describe this work more in detail in a subsequent article.

The plant was built under the supervision of Mr. J. A. Atwood, chief engineer of the Pittsburg & Lake Erie Railroad, and Mr. A. R. Raymer, assistant chief engineer, from the plans of Messrs. Westinghouse, Church, Kerr & Company, who were engineers and contractors for the entire equipment.

(To be continued.)

Heaters in Powerhouse for Hot-Water Heating System.

Test of a De Laval Steam Turbine Using Superheated Steam.

The attention of engineers has been drawn frequently to the fact that a steam turbine is particularly adapted to use superheated steam. The works of the De Laval Steam Turbine Company, at Trenton, N. J., are driven by electrical power generated by dynamos directly connected to De Laval steam turbines. The steam is supplied by Babcock & Wilcox boilers equipped with superheaters made by the boiler company. A short time ago Messrs. Dean & Main, Engineers, of Boston, Mass., made an elaborate series of tests upon a 300 brake-horse-power De Laval turbine operated at various loads and using saturated and superheated steam. With superheated steam, 13.94 pounds were consumed per brake-horse-power per hour and with saturated steam, 15.17 pounds per brake-horse-power per hour, the saving by the use of superheated steam amounting to 8.8 per cent. The amount of superheating was 84 degrees Fahrenheit. The details of these remarkably interesting tests are given in the following report of Messrs. Dean & Main, which is printed through the courtesy of the De Laval Company:

On May 21, 22, 23 and June 10, 1902, we conducted several trials under various conditions, of a 300-brake horse-power De Laval Steam Turbine, which is in operation at your factory in Trenton, N. J.

The turbine shaft is geared into two other shafts, instead of one, as is frequently the case with De Laval turbines, and on each of the latter shafts there is a direct current electric generator, both revolving in the same direction, and operating in series.

The current generated is used for driving the tools in the machine shop where turbines are manufactured, but the capacity of the shop is not at present sufficient to utilize the whole power of the turbine or generators. The excess load over the shop requirements was taken up by a water rheostat, which also served the purpose, by frequent adjustment, of maintaining a uniform load. The load could not be kept strictly uniform, but was sufficiently so for all practical purposes. The three-nozzle test on June 10 was made in the evening and the load was all absorbed by the rheostat and was uniform.

Steam was supplied to the turbine by a 250 horse-power Babcock & Wilcox boiler, with the same company's superheater attached, and operated at a pressure of about 200 pounds by the gauge. There were two of these boilers in the room, but that supplying steam to the turbine was separated from the other by disconnecting steam, feed, blow-off and drain pipes, and blanking them in such a way that there were no losses or gains of water from leakage. All work in the shop by steam, independent of that done by the turbine under test, was carried on by another boiler.

Several of the tests were made with superheated steam and several without, as stated in the detailed results of the tests. This could be conveniently done as the Babcock & Wilcox superheater can be thrown out of use at any time and the pipes forming it filled with water so as to add to the water heating surface of the boiler.

The De Laval Turbine.—The De Laval steam turbine consists of a single disc with properly formed buckets on the circumference, against which steam impinges at a proper angle. The steam enters a ring-shaped chamber surrounding the casing of the turbine and cast in one piece with it, and from this it enters several nozzles that convey the steam to the turbine buckets. These nozzles are formed in a way that has been found to be most suitable for the purpose, the interior being tapered with the large end towards the buckets. The steam in passing through the nozzles freely expands, thereby acquires velocity, gives up its work by impact upon the buckets, and thereby rotates the turbine wheel. It is apparent from this brief description of the process of obtaining the energy from the steam that if the means of

converting the energy of the impact into useful work are sufficiently good the efficiency of the machine will be high. There are many sources of loss to which the reciprocating engine is subject that are not present in the steam turbine, and, of course, to some extent, vice versa. In the case of the turbine the nozzles are not in contact with the turbine buckets, and therefore if economy once exists it will be maintained indefinitely.

The power of the turbine depends upon the number of nozzles in action, and these nozzles can be opened or closed by a hand wheel on each. The machine tested had twelve nozzles, but seven gave the rated capacity. It will be seen from this that the turbine is capable of great overloads. Regulation of speed is accomplished by a throttling valve operated by a centrifugal governor.

In connection with economy of steam and the ability to throw nozzles into and out of action, it is at once apparent that each nozzle performs its function as perfectly when operating alone as when any other number of nozzles is in operation. For this reason the turbine does not change its economy of steam per indicated horse-power, if such could be determined, as does a reciprocating engine. There is no "range of temperature" of any importance in the turbine to cause condensation of steam. The principal cause of diminished economy with lighter loads than the rated load is the fact of constant friction with all loads. At overloads there is even greater economy than with the rated load for the reason that the extra nozzles are of maximum economy and the friction losses are constant.

The turbine exhausted into a Worthington injector condenser, and the vacuum was measured by means of a mercury column connected into the exhaust chamber of the turbine. The turbine rotates very rapidly and the speed is reduced by the employment of a spiral spur pinion on the turbine shaft gearing into one or two spiral gears, as the case may be, depending upon whether the power is desired on one or two shafts. The pinions and gear are both double with the teeth inclined in opposite directions so that there will be no end thrust to either shaft.

The Water Measurements.—The water used by the boiler to make steam for the turbine was weighed in a barrel resting upon an elevated platform scale, and from the barrel it was emptied into a barrel below. From the lower barrel the water was forced into the boiler by an injector which was worked by steam from the same boiler, correction for the overflow when starting the injector being made. The height of the water when starting a test was noted by tying a string around the water glass, the height of which was measured in order to re-establish the height when desired.

The water quantities were determined for each hour separately during the tests, and with such uniformity in amounts, that one hour would have been sufficient to approximately establish the rate of consumption of the turbine if such had been necessary. From the tables, however, it will be seen that longer periods were employed. The hourly quantities are given because it is a matter of interest to know with what degree of uniformity hourly results can be obtained. The final averages, however, should only form the means of judging of the economy of the turbine.

When superheated steam was used the amount of superheat was determined by a bare stem Green thermometer inserted in a well of cylinder oil in the steam pipe between the throttle and the governor valves. When saturated steam was used the amount of moisture therein was determined by a Peabody throttling calorimeter drawing steam from the same place. The calorimeter discharge was weighed and deducted.

A separator was located in the line of steam pipe near the turbine. When superheated steam was used no condensation was weighed from the separator, but when saturated steam was used a quantity was continually discharged. This was weighed and deducted from the turbine consumption. There was a drain from the chamber which supplied the turbine nozzles, but it was considered that such steam, having once entered the apparatus undergoing the test, should not be deducted from the water weighed. It accordingly was trapped and the discharge allowed to waste. There was a slight drip from a small pipe at the bottom of the main steam pipe. This was of little consequence, but was nevertheless caught and deducted from the weighed water.

The Electrical Tests.—The power, the measurement of which was desired, was the brake horse-power of the turbine, as it might have been measured by some form of friction brake simultaneously applied to each shaft on which the electric generators were secured. For this purpose the generators might have been disconnected by means of a flanged coupling in each shaft, but as the electrical power was needed for operating the shop, the generators were used and their efficiencies determined. The electrical measurements were made by nice instruments and their errors were determined by taking them to the works of the Weston Electrical Instrument Company, Waverly Park, N. J.

The efficiencies of the generators were ascertained for each load carried. The friction of generators was determined by driving them as motors for another generator. Other resistances were computed by well known methods and under the actual condition of temperature, speed and output. Into these features of the tests this report does not enter, as the steam consumption per brake horse-power, only, is desired. The electrical data were taken simultaneously by one of our assistants and by the electrical engineer of the De Laval Steam Turbine Company. The computations for powers, efficiencies and brake horse-powers, were made by Messrs. Stone & Webster, of Boston, and by the De Laval electrical engineer.

Regulation of Speed.—No tests were made to ascertain the instantaneous effect in speed of change of load or to see how quickly the normal speed was regained after a change. In regard to the permanent effect of change of load on speed, this can best be observed from the data given in the tables of results further on. The speeds and loads are here tabulated for convenience with percentages of variations of load and speed referred to these with eight nozzles in operation.

Effect of Superheated Steam.—By comparing the results of the tests with superheated and saturated steam, the saving by the use of the former can be determined for the particular amount of superheat existing. As the tables show, the superheat steadily diminished as the load became lighter. This was caused by the fire and draft being very light with the lighter loads. The superheat for the eight-nozzle load averaged 84 degrees Fahr., while that for the five-nozzle load only averaged 16 degrees Fahr. There is, therefore, scarcely any propriety in making a comparison for the effect of superheat, except with eight and seven-nozzle loads.

Table Showing the Saving by the Use of Superheated Steam for Eight and Seven Nozzle Loads.

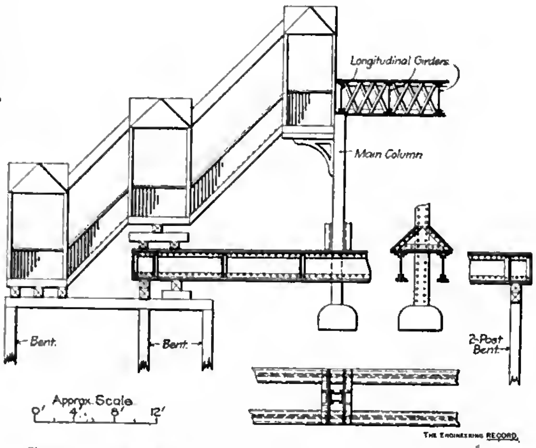
Nozzles in use.	Amount of superheat, deg. Fahr.	Load with superheated steam, H.-P.	Load with saturated steam, H.-P.	Steam per B.H.P. with superheated steam, lbs.	Dry steam per B.H.P. with saturated steam. lbs.	Saving by use of superheated steam. per cent.
8	84	352	333	13.94	15.17	8.8
7	64	298	285	14.35	15.56	8.4

In all of the statements made in this report of the consumption of superheated steam, the actual consumption without reduction to dry saturated steam as a standard, is given. This is customary, while with the results by saturated steam the moisture is deducted.

The Second Division of the New York Rapid Transit Railroad.—III.

The columns carrying the tracks and 42nd Street station platforms of the Sixth Avenue elevated railroad and two of the entrance stairways are located over the south side of the subway and directly over the open trench from which the excavation was made. The stairway and columns were first supported over the southwest corner of the street intersection by plate girders, wooden beams and trestle-bents, as indicated in the accompanying diagram, so that the stairway was maintained in service and the elevated structure carried its train traffic without interruption or modification.

The main trench in 42nd Street was first opened west of Sixth Avenue. Before it was opened under the west elevated stairway two narrow pits were dug across its axis, carried down to sub-grade, and their bottoms covered with sections of the subway floor. These pits were about 20 feet on each side of the column which supported the elevated railroad structure at the street corner, and in each of them a trestle bent of 12x12-inch timber was set with its cap about 5 feet above the street level. On these trestles, about 15 inches apart in the clear, were set two plate girders, about 3 feet deep, one on each side of the column and parallel to the axis of the trench. Two vertical transverse plates with flange angles on all sides were set across the top flanges of the girders and were field riveted to them and to the opposite faces of the column, through holes from which rivets in the cover plates had been cut out. This provided side brackets by which the column was securely supported on the girders. One end of the girders projected under the middle landing in the stairway, its floorbeams were blocked up from the top flanges of the girders and the short supporting column removed. Additional transverse pits were dug in the line of the trench and more trestle-bents set in them from which were supported wooden beams parallel to the plate girders and just below the street level. These beams carried at one end crossbeams supporting the lower landing and foot of the stairway, and near the opposite end had crossbeams wedged up against the lower flanges of the plate girders to reduce their span and give additional direct support to the middle of the stairway. After all the beams and girders were set the trench was completed and the main column left suspended above it. After the subway structure is completed a solid masonry pier will be built on its roof to carry the two columns and the lower landing of the stairs. The stairway and columns at the northwest corner of 42nd Street and Sixth avenue were supported over the subway excavations in a similar manner, as will be the two stairways on the east side of Sixth Avenue.

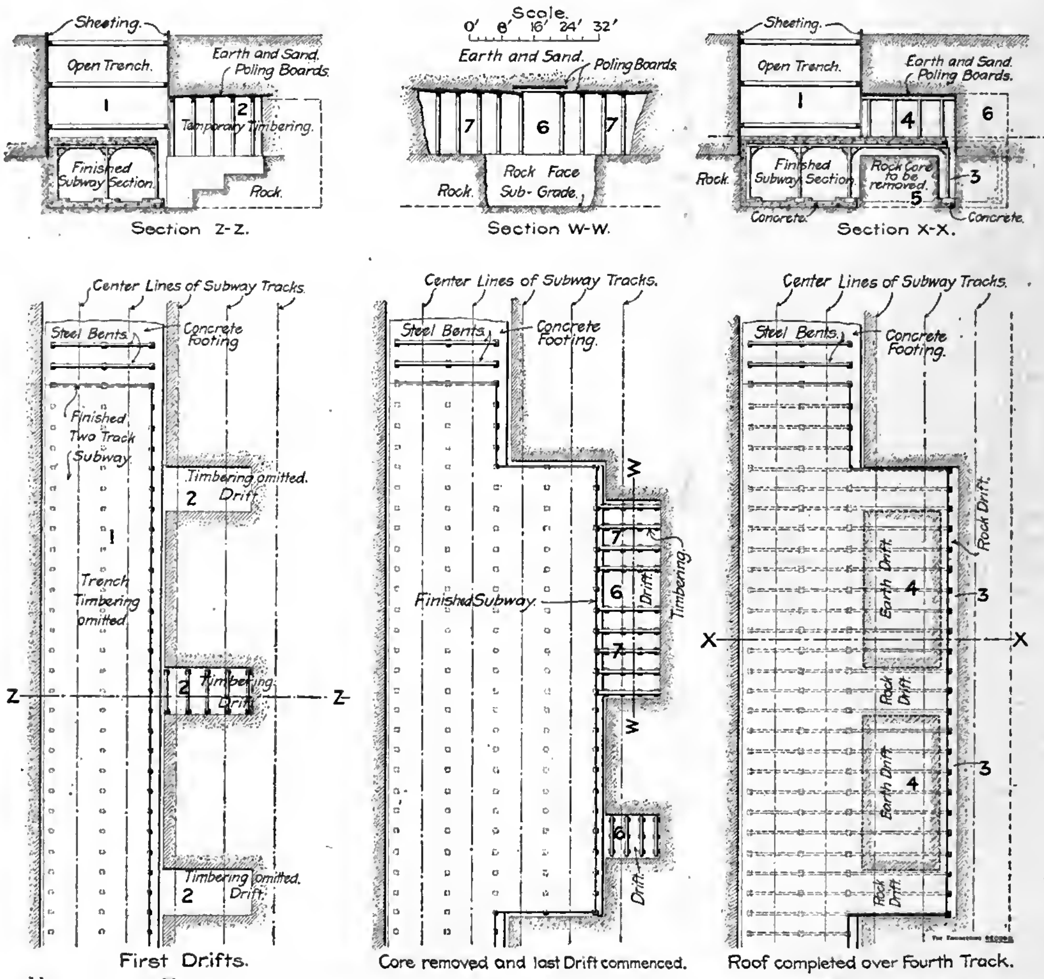


Supports of Elevated Railway Station.

The excavation for the subway between Fifth and Sixth Avenues was commenced from a long trench about 20 feet wide on the south side of the street, by driving a transverse drift about 12 feet wide on the north side of the subway and constructing in it two complete panels of the subway. The excavation was widened out two bents east and west and timbered and the subway construction continued. It was intended to proceed in this way, but the timbering was found to be too expensive and this method was superseded by the method with the 24-inch I-beams and roof poling boards described last week.

On 42nd Street between Fifth Avenue and Madison Avenue there are five tracks and the structure is widened for the 42nd Street depot. The excavation is about 35 feet below the curb, extends 10 to 15 feet into the rock and was made by a special method not employed elsewhere on the line. A trench marked 1 in the diagram, was first opened to sub-grade the same as elsewhere on 42nd Street, but it was made about 30 feet wide and in it was built the subway structure complete for two tracks. Transverse drifts marked 2, 12 feet wide and 50 feet apart on centers, were drifted from the north side of the trench to just beyond the fourth track. They were made about 4 feet higher than the level of the subway roof and their floor was the surface of the rock.

The north ends of these drifts were connected by similar longitudinal drifts marked 3, which were 7 feet wide, parallel with the axis of the subway and the rock bottom was drilled and blasted to sub-grade in all the drifts, care being taken to work between the vertical timbers and leave them seated on ledges on each side so as to support the roof from the original surface of the rock. The bottom of drift 3 was covered with a section of the finished subway floor, and on it was set the third row of columns, which, in this special case, was 25 feet from the second row. The original drifts, 2, 2, were then extended east and west by working faces on both sides of them until they met and left the whole roof of poling boards supported on vertical timbers about 10 feet long set on the rock surface, which was for the present left undisturbed. This portion of the earth excavation is marked 4 on the plan and after it was completed the 25-foot roof beams were erected on the second and third rows of columns and the concrete was laid on them to complete the roof over the south four tracks. After the roof was completed the columns were protected by timber shields and the core of the rock marked 5 in the cross-section X X was blasted out to sub-grade and the floor concrete laid there. The original drifts, 2, 2, were extended to the north edge of the subway, as shown at 6, 6 in the plan, and then their sides were excavated east and west in drifts marked 7, 7, in the plan and in section W W. The rock bottom having been blasted out, the



Method of Excavation on Forty-Second Street between Fifth and Madison Avenues.

excavation was completed and the remainder of the subway structure was built.

In these operations the earth and rock was wheeled to the drifts, 2, 2 2, and loaded on narrow-gauge cars on transverse tracks which transferred them to the south side of the tunnel where suitable holes had been left in the roof to allow them to be hoisted out by the cableways. The work at this point was complicated by the special provisions for connection with the Park Avenue tunnels at the east end and for the enlargement for the depot, and was successfully executed with minimum obstruction to the heavy traffic overhead and around the entrance to the Grand Central Station. The street car service was uninterrupted and the street was not obstructed except on the extreme south side. Here as elsewhere the roof timbers and poling boards were left permanently in place and were thoroughly wedged up on brick piers built on top of the subway roof.

A 4-foot water main in Madison Avenue is temporarily supported across the south trench of the 42nd Street subway by a pair of triangular combination trusses from the lower chords of which it was suspended before the rock underneath it was removed. The trusses each have an 8x8-inch horizontal bottom chord about 30 feet long with inclined top chord sections which run from the ends of the bottom chord to meet at the vertex about 12 feet above its center point. The truss is divided into four equal panels by vertical tension rods having nut bearings and washers on flat wooden blocks at the lower ends and on wooden angle blocks at the upper ends. The middle vertical is composed of two 1-inch, and the end verticals are each composed of one 1-inch rods. Diagonal struts are run from the tops of the end verticals to the bottom of the middle vertical, and below the tops of these diagonals the top chord is reinforced by a 2x6-inch plank on the under side, the upper end of which serves as an angle block to receive the thrust of the diagonal. The two trusses are braced together about 3 feet apart over all by pieces nailed to the top chords and by 8x8-inch cross beams supported on the bottom chords. Holes are bored through these cross beams, just outside the bottom chords and 1-inch vertical eyebolts are passed through them and have nut bearings on the tops of the beams. A chain is attached to the eyes in the lower ends of each pair of rods and engages the water main at a joint. By screwing up the nuts on the upper ends of the rods the main was lifted free of its original support and is maintained clear of the subway until permanent piers are prepared for it on the subway roof.

Architectural and Structural Steel Draftsmen are wanted by the Navy Department and examinations will be held on August 19 and 20 at Pittsburg and Chicago. Circulars giving information concerning the positions and examinations can be obtained from the Secretary of the Navy.

Yellow Pine and Puget Sound Fir have been tested on a large scale by Naval Constructor F. W. Hibbs, who described his experiments and summarized their results at a recent meeting of the Pacific Northwest Society of Engineers. Yellow pine proved more brittle and better able to withstand wear, owing to the large amount of pitch it contains. Fir is more fibrous and better adapted for beams and tension members. In tension tests the pine cracked and pulled apart, while the fir twisted like a rope and the fibers stood out like strings. The tests were made with green lumber, as well as that which had been air-seasoned and kiln-dried.

The Loss of Capacity of the Vyrnwy Aqueduct, Liverpool, England.

The water supply of Liverpool comes from three sources, the Vyrnwy reservoir, the Rivington reservoirs, and from wells in the vicinity of the city, the first of these furnishing nearly half of the total supply, which during 1901 was at an average rate of 27,800,000 imperial gallons per day. The aqueduct carrying the water from Vyrnwy to the Prescot reservoirs at Liverpool is 68 miles long. At Oswestry, about 17 miles from the reservoir, the water is filtered through 2 to 2½ feet of sand in order to remove suspended particles and discoloration produced mainly by iron and peat.

Soon after the Vyrnwy aqueduct was put in use in 1892, it was found that the capacity of that part from the inlet to Oswestry was decreasing to a very noticeable extent, while for the remainder of the distance to Prescot it remained practically constant. Mr. Joseph Parry, M. Inst. C. E., chief engineer of the waterworks, believed at first that the reduction in capacity was due chiefly to accumulations of air, but the results following the introduction of additional air valves did not confirm this view. One day when he happened to be on the aqueduct line a pipe burst and discharged an immense quantity of a black deposit. Samples were sent for analysis to the city's chemist and bacteriologist, and an investigation was started which showed that the decreased capacity was due to this deposit. The rapidity with which it formed is shown by the fact that in November, 1898, after a thorough cleaning out of this deposit, the measured discharge to Oswestry was 16,530,000 imperial gallons per day, and by the middle of June, 1900, the delivery had fallen off, notwithstanding frequent sluicings, to 13,970,000 imperial gallons. A partial cleaning out of the deposit then resulted in an increase of a million imperial gallons per day, but by the end of October, 1901, it had fallen again to 13,770,000 imperial gallons. Since then nearly the whole length has been cleaned, resulting in a discharge nearly up to what it was originally.

On February 25, 1899, an experimental plant was put in operation near the outlet of the Hirnant tunnel, about 2¼ miles from Lake Vyrnwy, in order to determine the effect of adding lime to the raw water. The treated and untreated water was delivered into two parallel and similar lines of 4-inch cast iron pipes. After being in operation for six months the pipes were taken up for examination. Both lines of pipe contained in about the same quantity thin deposits of the slime observed in the large pipes. It was then decided to increase the proportion of lime so as to make the water quite neutral or very faintly alkaline, and to place small sand filters in each of the two lines of pipe. The filters were put in operation November 17, 1899, and there was also added to the untreated side near the inlet a fine copper gauze screen. On April 19, 1900, when the pipes were again taken up for examination, there was found in the short lengths between the intake and the lime cylinder and screen respectively, abundant evidence of the deposits. After the lime treatment the pipes were substantially free from slime before filtration, and absolutely free after filtration. On the untreated side there was slime between the screen and the filter, but none beyond the filter. The next examination was on September 24, 1900, when it was found that the lengths between the lime cylinder and the filter were free from the black slimy deposits, but on the untreated side there was red slime and jelly-like growth occasionally to be found. After filtration the pipes on both sides showed neither slime nor deposit. It was then decided to discontinue the lime treatment, but to continue the experiments with the filters. The latter had up to this time been composed of sand obtained from the river bed screened through a ⅛-inch mesh sieve. They were subsequently remade with crushed Silurian rock of various degrees of coarseness.

A centrifuge was used to determine the relative amounts of suspended matter at different stages of the experiments. The diameter of the centrifuge was 18 inches, and it was run by an electric motor at from 2,000 to 3,000 revolutions per minute. The following figures give the suspended matter from samples taken February 8, 1901, in parts per 2,750, and February 25, 1901, in parts per 2,740:

	Raw water.	Screened.	Filtered.	Screened and filtered.
Feb. 8	39	9	6	3
Feb. 25	28	12	4	13

In a paper published recently in the Thomson-Yates Laboratories Reports Professor Robert Boyce, the consulting bacteriologist of the works, deals with his investigations on the Vyrnwy water. He states that wherever the deposit occurs in the unfiltered water, whether in Lake Vyrnwy, or along the aqueduct or at Oswestry, the appearances under the microscope are essentially the same. The bulk of the deposit consists of irregular flakes of a soft material of a characteristic golden-brown color, numerous silicious particles, a considerable amount of vegetable debris, but remarkably few green algæ of any kind. The higher green forms of aquatic plants are also conspicuous by their absence from the lake. The number of bacteria present is comparatively small, and this is corroborated by the culture experiments which have been made on an extended scale. The golden-brown irregular masses have imbedded in them or sticking to them all kinds of debris. They are soft and appear to be composed of some gelatinous material impregnated with the yellow oxide of iron. They often show no trace of structure, but flakes will be met with which, on very careful examination with high power, show passing through them one or more distinct hyphæ.

When the material which clings to the copper gauze screen is examined, the hyphal character of the flakes is much more evident, and long, unbranched threads can be seen possessing a greater or less amount of sheath. Prof. J. Campbell Brown, the analytical chemist to the water department, has drawn attention to this organism, and there is every probability that it is a gelatinous iron-forming thread fungus of the Cladothrix, Leptothrix, Crenothrix group. In none of the deposits which Professor Boyce examined has he been able to detect active growths of the organism; it almost invariably occurs in the short, irregular, broken fragments or flakes described above. A most remarkable feature is that the gelatinous material appears to increase with age; it is not on the actively growing filaments that it is most abundant, but it is thickest on the broken and apparently dead fragments. As regards the relation of the organism to the iron in the water he says there are numerous examples of bacterial activity leading to the oxidation of dissolved iron, and a group of organisms have been called "Iron" and "Manganese" bacteria from their power of producing the oxide of these metals from the soluble forms dissolved in the water. T this group Crenothrix and allied thread forms, including the present one, belong, and if Winogradsky is correct, the filament absorbs the soluble iron salt and deposits the oxide in its sheath.

The history of the deposit he gives as follows: "The iron fungus grows in some parts of the watershed, fragments are carried with other debris into the lake, and they fall to the bottom; other larger and younger threads float in the water of the lake and are caught on the copper gauze strainer; innumerable small fragments, however, pass through the strainer into the aqueduct, and gradually collect at the sides and form a coat on the brickwork, wood or iron of the pipe. Their gelatinous nature facilitates their adhesion, and they entangle with them all kinds of other debris, as sand, diatoms, etc. Not all the particles are deposited on the sides of the pipe line; some pass on with the water into the reservoir at Oswestry, and no doubt also particles are continually being detached from the surface of the aqueduct. But the filters remove them. In so far as the dark color of the unfiltered water is due to the presence of particles of the dark red fungus held in suspension, it is clear that the mechanical filtration will help to remove the color. But the dark tint remains after the particles have been removed, this color being due partly to the presence of some organic coloring matter, and partly to the presence of some iron compound in solution."

In a report by Dr. Brown, dated December 9, 1901, the deposits in the Vyrnwy aqueduct are divided into three kinds: (1) Incrustations derived mainly from corrosion, (2) organisms growing on the inner surface, and (3) accumulations of debris attached to these organisms, both mineral and organic.

The second division is the most interesting one, and the following statements from Dr. Brown's report show how the growth takes place: "When a protected pipe is laid down and Vyrnwy water sent through it, little masses of jelly begin to form and gradually enlarge on the inside surface of the pipe. In this jelly there are centers of growth—later there are growing threads which lengthen and twist. The older portions of these or other threads straighten out and acquire a sheath, and in this sheath a ferruginous deposit accumulates and thickens. I presume it ultimately kills the older end. Certainly the tip grows as a projecting thread, while the rest becomes a foxy-red mass of inextricably intertwined ferruginous sheaths. These are attached to the pipe, but portions break off and are carried forward from the tunnel and the pipes as well as the lake. The successive appearance of all these forms has been traced in the experimental pipes at Hirnant.

"In the slime are black particles formed of binoxide and other oxides of manganese. I have come to the conclusion that the dark manganese particles grow by chemical action from the materials present in minute proportions in the water. Some of the ferruginous particles also may be the result of chemical decomposition of the constituents of the water, but a very considerable proportion of them is the result of the accumulation and breaking up of the old organisms, similar in principle though differing in detail from the accumulation of coral."

Dr. Brown states further: "I have proved by observation and experiment that the Vyrnwy organisms can live upon organic matter in water containing no iron, while if iron compounds are present in the water, ferruginous matter is deposited in their sheaths. In Vyrnwy there is no ferrous carbonate. There is a soluble organic compound of iron.

"In some waters having some of the characters of Vyrnwy similar growths occur. In other waters coming from similar gathering grounds, but not containing the organic compounds of iron found in Vyrnwy, there is no similar slime. In certain waters having neither iron nor acidity, but containing peat, there is no similar slime. Various analyses of the slime have been sent in, showing great variations in the proportions of silicious and clay particles and of the ferruginous organic debris. There are no particles of peat in the slime."

A number of schemes have been proposed to prevent this troublesome growth in the aqueduct between Lake Vyrnwy and Oswestry, among which a system of screening and rough filtration is held by Mr. Parry to be most promising. The subject is of so much importance that it occupies the larger part of Mr. Parry's 1901 report, from which the preceding account has been prepared. He hopes to explain shortly at greater length and with technical details the course of the investigation and the conclusions to be drawn.

Concrete Sewer Construction at the Chicago Clearing Yards.

The switching yards of the Chicago Transfer & Clearing Company, southwest of the city, occupy some 4,000 acres of land bounded on the north and south by 63rd and 79th Streets respectively, and extending westward from the city limits about five miles to the Chicago Drainage Canal. This territory before the construction of the Clearing Yards was almost a dead level, at a general elevation of about 27½ feet above Lake Michigan datum, and was practically without natural drainage. At the extreme western portion of the land there is a sudden drop in elevation of about 15 feet to the old Illinios & Michigan Canal. To the east there is a slight, almost uniform slope to the lake, a distance of about ten miles. To the north and south there is no natural watercourse within a range of some miles. As a preliminary operation to building the Clearing Yards, it was decided to drain the whole area and to raise the level of the yard site about 2½ feet by filling in with sand. The construction of the main sewers, which were of concrete laid in open trench which for over a mile averaged 24 feet in depth, is described in a paper by Mr. E. J. McCaustland, recently printed in the "Transactions" of the Association of Civil Engineers of Cornell University, from which the following account has been condensed:

It was decided to drain the entire territory into the Illinois & Michigan Canal, this being the only outlet within the range of economic possibility. After a consideration of the conditions, Mr. A. W. Swanitz, chief engineer of the company, decided to use concrete for everything 36 inches in diameter and over. Broken stone could be had at a reasonable figure and in unlimited quantities, while brick was high and deliveries uncertain. The cost of labor for concrete construction would be but a fraction of the cost for brick construction. Furthermore, aside from the question of first cost and facility of construction, it was believed that a monolithic main of large diameter, built under proper supervision, would prove more durable and reliable than if constructed of blocks; that the interior of such a main would present less resistance to flow in time of flood, and would be more easily kept clean by the extremely limited dry weather flow.

The width of trenching at the surface varied from 14 feet for the 90-inch to 7 feet for the 36-inch mains. The excavation on the entire line of concrete main was done by steam shovel, supplemented, in the deeper trenches by derricks operated by steam. Two styles of steam shovel were used on the work, one a 75-ton machine made by the Vulcan Iron Works of Toledo, Ohio, used for the wider and deeper trenches, and the other a lighter machine built by the Bucyrus Company, of Milwaukee, Wis. The excavation was mostly in a blue clay containing occasional small water seams and overtopped with a surface layer of about 2 feet of black soil. When using a steam shovel sheeting and bracing can be put in place only after the shovel has removed all material within reach and is ready to move forward; hence such a method of excavation would not be suitable in cases where the sheeting must be carried down with the excavation. The material excavated was deposited upon the bank alongside the ditch, except for a few thousand yards which were dumped from the shovel bucket directly on flat cars and used for filling.

In preparing for work the trucks were removed from the shovels and they were mounted on heavy timbers crossing the trench and resting on sills which in turn were borne upon wooden rollers running on plank runways. The machines were thus placed in the most advantageous positions for work; they were moved forward by their own engines hauling in a cable attached to a dead-man ahead. The Vulcan shovel cut the larger trench to a depth varying from 18 to 22 feet; however, a reach of more than 20 feet is not considered wise in hard digging, since it induces excessive stresses in the machine. A 2-yard bucket was first used, but it was found that better progress could be made with a smaller one, there being less liability of overstraining the machine and causing breakdowns.

The work done by the shovels is shown in the accompanying table. The figures are close averages, and may be relied upon to approximate closely the amount of work these types of shovels may be expected to do under ordinary circumstances where there is little trouble to be apprehended from caving. On some days the Vulcan shovel reached a figure nearly double the average given, but such work was exceptional.

Diam. sewer, in......	90 and 84	48	42	36
Length trench, ft.....	6,400	4,540	2,660	3,340
Av. width, ft........	12.5	8	7	6
Av. depth, ft.........	20	17	14	11
Av. lin. ft. per 10 hrs.	69.8	98	85	120
Av. cu. yds. per 10 hrs.	640	500	310	300

Note.—The Vulcan shovel with 1½-yard bucket was used on the 48, 84 and 90-inch sewers, and the Bucyrus shovel with ¾-yard bucket, on the 42 and 36-inch sewers.

The deeper trenches, for the 90 and 84-inch mains were cut by the shovel to a depth of only 20 feet; this left from two to four feet to be removed from the bottom by some other means. The removal was accomplished by using an ordinary swinging boom derrick mounted on a turntable directly over the trench, with a boom of such length as would give control of about 30 feet of ditch. The hoist was operated by steam and all the movements of boom and derrick were under control of the engineer. Usually twelve men were in the trench in groups of four, filling the buckets. Four wooden buckets were in use, holding about two yards each; three of these were in the trench at all times, the gangs working in regular order so as to keep the hoist always busy. The buckets were rectangular in both plan and elevation, and consisted of a bottom and three sides. The sling for the bucket consisted of three short chains attached to a ring which was held by a hook to the hoisting tackle, one of these chains being provided with a trip hook for dumping the bucket. In taking out a 4-foot bottom for the 90-inch sewer, working in a hard blue clay where the invert was carefully trimmed to fit the external form, a gang of twelve men could easily complete a length of 100 feet in a day of 10 hours. Very little loosening of the soil with the pick was done; digging with good, round-pointed, short-handled shovels, using foot irons, was more effective. In the shallower trenches the derrick was used only to remove the material cut out in shaping the invert.

The thickness of the 90 and 84-inch sewers was 12 inches; of the 48-inch sewer 10 inches, and of the 42 and 36-inch sewers 8 inches. A ½-inch coat of plaster was put on the inside except on the upper quadrant. The concrete was a 1:3:5 mixture, proportions by volume. The stone was a clean limestone furnished by the Chicago Crushed Stone Company, and was in two sizes varying from 1 to 2½ inches and ½ to 1½ inches. These two sizes of stone were used in equal proportions at first, but later were mixed in the proportion of 1 of the larger size to 2 of the smaller. The sand used for concrete was the kind known in Chicago and vicinity as "torpedo" sand. It is in reality a very fine angular gravel with an admixture of some coarse sharp sand, and is in all particulars a first class material for concrete work. The stone cost delivered about 80 cents per cubic yard, and the sand about 90 cents. The cement used was the Illinois Steel Company's Steel Puzzolan, costing $1.30 per barrel delivered, and passed the usual tests in a very satisfactory manner.

To mix the concrete, a rotary machine was used, the type being that with horizontal shaft and radial arms or knives set spirally so that a revolution of the shaft would not only mix the material thoroughly, but would force it forward through the machine. It was mounted on a flat car and run on a track, used as a supply track, which was laid along the line of the trench as the work progressed; an independent engine with upright boiler, mounted on the same car, furnished the motive power for the operation of the mixer. Usually the material supply train was made up with the mixer car in the middle, three cars of stone in front, and two of sand and one of cement in the rear. An ordinary day's run would use up something over two cars of stone and about one and one-half of sand. A 60-ton yard engine was kept by the contractor to make up the supply train and keep the mixer as near as possible to section under construction. Runways of plank, supported on detachable brackets, were arranged along the side and at the top of the cars containing the crushed stone and sand. Iron body wheelbarrows were used to transport the material to the mixer and the loading of the barrows was made to conform as nearly as possible to 3 cubic feet of sand and 2½ cubic feet of stone; two barrows of stone being thrown in to one barrow of sand and one cubic foot of cement added. The proper amount of water was discharged from a hose under the control of a workman and the whole became thoroughly mixed in passing through the machine. The operation was continuous, and the uniformity of incorporation of the aggregate with the mortar was excellent.

The concrete was deposited by transporting from mixer to trench in wheelbarrows, and dumping through open chutes to the bottom. Owing to the long drop some tendency was developed for the larger stones in the aggregate to become separated from the mortar. It was found, however, that a single workman with a shovel could easily restore almost perfect homogeneity by a few well directed efforts upon each barrowful as it was dropped. This, of course, was a most important detail for the inspector to keep within bounds; and it is believed that some form of gravity mixer would be more satisfactory for such deep trench work, and much cheaper to operate.

The bottom of the trench was cut to the form of the exterior circumference of the sewer ring by means of templets. The invert was put in place in layers and tamped until free water appeared on the surface. The ring was carried up on the sides until the invert occupied about 140 degrees of arc.

The centering for the arch was carried loosely on ribs made circular in form to rest on the invert and with allowance for the lagging over the 220 degrees of arc above the invert. The lagging was of 3x2-inch material in 16 or 12-foot lengths, the edges chamfered to give radial joints. The strips were held in place on the ribs by a 3/16x2-inch iron band passing over them at the end ribs and bent up under the two outside strips, forming a hook to support the lower ones, on which all the others rested. When the centering was in place and keyed up tight the concrete was deposited on top of the finished invert and carried up as far as the proximity of the trench walls would justify. When a height was attained beyond which the sides of the trench would no longer serve as a form, planks were inserted and braced against the trench walls until the arch was carried up at least 30 degrees above the springing line. Beyond this, form was preserved by use of a templet at the forward end and the finished sewer ring at the rear.

As soon as a length of arch was completed and thoroughly tamped, all form planks were removed from the trench and a light covering of surface soil was deposited over the green concrete to protect it from the wind and sun. The centers were usually removed after 48 hours. This was easily accomplished by swinging the ribs about their vertical diameters and removing the lower strips of lagging first.

In performing the work the contractor furnished only the labor, tools, etc., all materials being supplied by the company. The quantities and prices were as follows:

Diam. sewer, in..	90	84	48	42	36
Depth trench, ft..	24	22	17	14	11
Length, ft.	5,400	1,000	4,540	2,660	3,340
Cost per foot.....	$6.68	$5.91	$3.57	$3.00	$2.30

In addition to this main concrete sewer, the contract included the construction of about 5 miles of vitrified pipe sewers ranging in size from 8 to 33 inches, together with the necessary manholes and catchbasins, which were of brick.

The backfilling of the trenches was done almost entirely by machine. A derrick of the same style as used in excavating the bottom, was mounted on timbers and rollers for ease of transport. The swinging boom was long enough to reach to the extreme limit of the spoil bank when the machine was located on the opposite side of the trench. The derrick was operated by a double drum, reversible hoisting engine with upright boiler, mounted on derrick platform. The bowl from an ordinary wheeled scraper was fitted with a bale in front to which a cable was attached by which it could be pulled forward, and in the rear a ring was fixed to which a light steel cable was attached. This cable passed around a sheave at the end of the boom, thence to the engine drum around which several turns were taken, and back again to the ring in scraper bowl. This cable served to pull the scraper back to position for loading, and, being endless, served to hold the bowl into any position as desired by the engine man. Handles were fixed to the bowl as for an ordinary drag scraper. Two men at these handles could hold the bowl in place for filling and the engine would pull it forward until filled. When this was accomplished, and the load drawn forward over the trench, the endless cable was held taut on the drum to prevent backward movement of the scraper and a slackening of the pulling rope would dump the load. This machine, with two men to operate it in addition to the engineer and fireman, could easily handle 900 cubic yards of earth per day. No tamping or puddling of backfilling was required. This machine was constructed from the designs of Mr. John Dowdle, of the firm of Nash & Dowdle, of Chicago, the contractors for the construction of the sewers.

The original plans for the work were prepared by Messrs. Alvord & Shields, Chicago; and Mr. C. W. Hotchkiss was chief engineer of the company when the work was undertaken. Before construction began, however, Mr. A. W. Swanitz was made chief engineer, and Mr. E. J. McCaustland principal assistant. It is stated that the plans underwent some modification after leaving the office of Alvord & Shields.

Erection of the Uganda Railway Viaducts.

On the Uganda railway between Kilindini on the east coast of Central Africa and Port Florence on Lake Victoria, there are about 12,000 lineal feet of single-track plate girder trestle viaducts which have a total weight of about 13,000,000 pounds and were built and erected by American contractors. The spans weigh about the same as the towers and generally alternate 20 and 40 feet in length. They have two lines of longitudinal plate girders 3 feet deep and about 8 feet apart, with laterals and angle-iron sway-brace frames but no floorbeams or stringers. The track rails are laid directly on the cross-ties, which overhang both sides of the girders and carry sidewalks with hand rails on both sides of the track. The towers, 20 feet long and 40 feet apart in the clear, each have two trestle bents with columns battered in the vertical transverse planes. They are from 20 to 120 feet high and are divided into panels of 20 feet or less, by longitudinal and transverse horizontal struts with pin-connected diagonal rods. All girders and compression members have field-riveted connections and their details conform to standard American practice, as approved by the English engineers. The tower columns have separate short masonry piers, and the girders are seated directly on their caps.

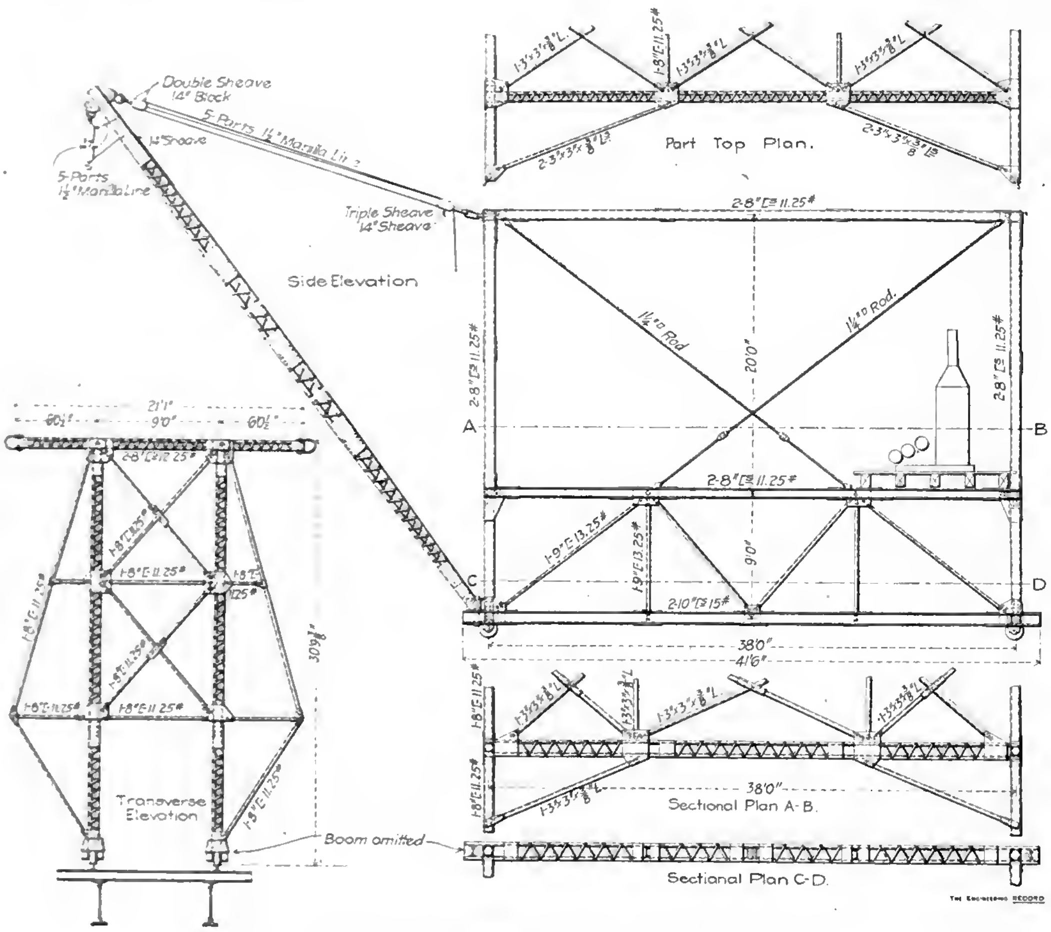
The superstructure was erected by an overhead steel tower traveler with two 70-foot booms which overhung the completed structure far enough to assemble a tower and two spans in advance. It had four vertical posts, 9 feet apart transversely and 38 feet apart longitudinally, which were braced together as shown, by horizontal struts and diagonals on all sides. The tower was about 40 feet high over all and traveled on a 9-foot gauge track with the rails laid on transverse 8-inch I-beams on top of the main longitudinal girders. There was a single 16-inch double-flange wheel under the foot of each vertical post with its axle set in cast iron journal boxes bolted to the under sides of the longitudinal sills. Transverse sills were omitted to give clearance through the traveler at rail level. The upper part of each transverse bent had two panels of X-bracing and the vertical posts were each strengthened by trussing on the outside which also served for outriggers to lead the lines which swung the derrick booms around their vertical axes.

The intermediate longitudinal horizontal struts were 9 feet above the sills and braced to them with zigzag angles virtually forming trusses, the end diagonals of which were continued with pin-connected sleevenut rods to the tops of the vertical posts. Transverse wooden beams across the top chords supported a working platform for the hoisting engine, boiler, coal, water and about ten tons of ballast for counterweight. There were complete lateral systems of horizontal transverse struts and X-braces in the planes of the top chords and of the tops of the vertical posts, all the members being composed of single angles with field-riveted or bolted connections. The vertical posts and principal struts were made of pairs of channels latticed, with jaw connections or double gusset plates.

Each of the forward vertical posts served as a mast for a derrick boom which had a horizontal pivot through a riveted foot-block revolving on a vertical pin which took bearing in the top and bottom cover plates of the projecting end of the sill. The boom was made in three sections of nearly equal length, which were spliced together with flange cover-plates, shop-riveted to the end of one section to form jaws which were field-riveted or bolted to the other section. The end sections were tapered, but the middle section was straight and could be omitted and the end sections spliced together without it to make a shorter and proportionately stronger boom. The links to receive the tackles were attached to eye bolts through the tops of the masts, and were set between pairs of plates riveted across the end of the boom and secured there by pins. The lead line from the hoisting tackle passed over a sheave set inside the boom near its upper end. The upper transverse struts projected 6 feet on each side of the traveler and had yokes on vertical pivots at the ends to receive guy lines led in any direction. The rear ends of the lower sills were clamped to the erected girders to afford an estimated reaction of 10,000 pounds against upward pull when the traveler was in service. The weight of the completed traveler was about 40,000 pounds and it had a capacity of 20,000 pounds, enabling it to handle a 5-ton longitudinal girder at the extremity of each boom.

The steel work for twenty-seven viaducts was manufactured at the Pencoyd shops of the American Bridge Company, and arrived at Port Kilindini about 45 days after shipment. It was erected by Mr. N. P. Jarrett and seven bridge erectors sent from the shops to do the derrick work and assembling, with from 200 to 300 natives to rivet and perform labor. Steel derricks were shipped with the viaducts and were first set up to unload the materials and afterwards their booms were taken for the traveler. As fast as the viaduct was erected a material track was laid on it between the traveler rails, and the members were run out on it to the last completed span and through and under the traveler, where there was a clearance 7½ feet wide and 10½ feet high which enabled the cars to deliver directly to the derrick booms.

According to "Indian Engineering," between the Kikuyu summit and the Great Rift Valley there are eight viaducts from 120 to 780 feet long and from 32 to 85 feet high which were erected by a traveler of different construction. It also was an overhead traveler, had a 60-foot fixed overhang and was apparently built entirely of timber except the diagonal tie rods. It had two longitudinal trusses about 10 feet high, 30 feet long and 10 feet apart, which were each mounted on two double-flange wheels at each end. At the forward end of the traveler two masts about 35 feet high were seated on the bottom chords of the trusses and overhung their ends about 5 feet at the top. They were guyed to the kneebraced ends of a transverse strut about 18 feet long on the top chord of the trusses and had back-stays to the rear ends of the bottom chords. The tops of the masts were connected by a horizontal strut and had diagonal rods to the ends and intermediate points of 60-foot inclined fixed booms, which were continuations of the forward diagonal braces in the trusses. The booms were king-post trussed on the under side between the intermediate guy and the traveler. Each boom had two tackles suspended from the end and two from the foot of the intermediate diagonal, and there were two tackles suspended from the head of each mast. The tackles were operated by windlasses on a floor laid across the top chords of the traveler trusses, under which there was clearance for the viaduct members to be delivered on trucks on a narrow gauge track between the traveler rails. They were unloaded by the mast tackles and fleeted out and lowered to position by the boom tackles. Views of the bridges during erection are given in the journal mentioned.



Steel Traveler for Erecting Viaducts on Uganda Railroad.

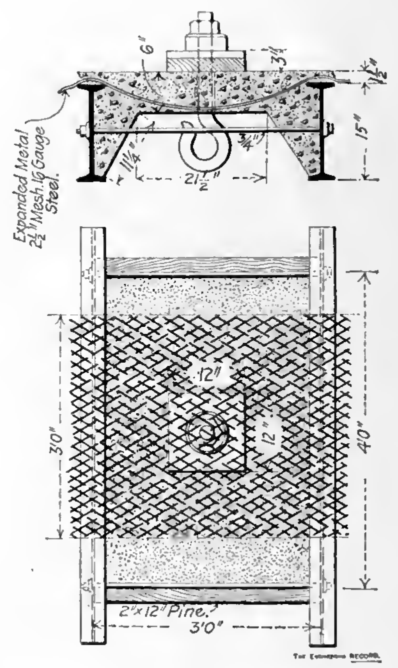
Test of a Concrete Slab Reinforced with Expanded Metal.

By O. W. Connet, Asst. City Eng., Baltimore.

In connection with plans to replace wooden floors on some bridges in Baltimore, it was decided to make a test to destruction of a 6-inch concrete slab, reinforced with expanded metal. The result of the test is such as to be of general interest and was made as follows:

Two 15-inch I-beams about 6 feet long were placed on top of two stout wooden trestles about 8 feet above the ground and fastened rigidly 3 feet apart center to center by two 2x12x35-inch plank 4 feet apart and by two ¾-inch bolts just inside the plank.

A form was made of 1-inch plank such that the concrete would be 6 inches thick for a width of 21½ inches, having a bearing on the lower flange and finishing 1½ inches above the top of the I-beams. The concrete was thoroughly rammed in between the form and I-beams and brought up to the proper position of the expanded metal, which was then laid across the top of the beams and bent down 4 inches in the center. A piece of 3-inch water pipe 5½ inches long was placed on end in the center of the slab and forced through one of the meshes of the expanded metal down onto the form, so that the top of the pipe finished ½ inch below the top of the concrete slab. The concrete was then filled in to the required thickness. The sheet of expanded metal used was No. 16 gauge steel, with 2½-inch mesh and was 4 feet long in the direction of across the beams by 3 feet in the other direction.



Test Block of Concrete.

The concrete was composed of one part American Portland cement (Nazareth), two parts clear fine river sand and four parts of crushed gneiss stone of a size to pass through a 1½-inch ring down to ¼-inch stone. After the concrete had set for seven days the form was removed and on the twenty-eighth day the test was made.

A washer of Georgia pine 12 inches square and 3 inches thick was laid directly over the hole in the center of the slab, and an iron washer 4 inches in outside diameter was placed on top of the wood; a 2-inch bolt with a hook on the lower end was put through these and held by a nut. Four strands of a ⅞-inch wire cable were suspended from the hook and passed around six iron gutter plates 5 by 6 feet 8 inches and ¾ inch thick. On these plates timbers and plank were arranged on which street paving block were piled until the bolt pulled a hole through the concrete.

After about 20 tons had been put on, three minute cracks began to show on the under side of the slab, radiating from the center in practically straight lines towards the corners of the slab. These did not increase perceptibly as the load was increased, and there was no deflection of the top of the slab before it failed.

When the slab failed the bolt pulled through carrying a conical shaped mass of concrete with it and tearing the expanded metal apart. The hole in the top of the slab was elliptical in shape, about 8x11 inches, while at the bottom it was more nearly square and about 20 inches on a side. The total concentrated load on the bolt at the time of failure was 28 tons.

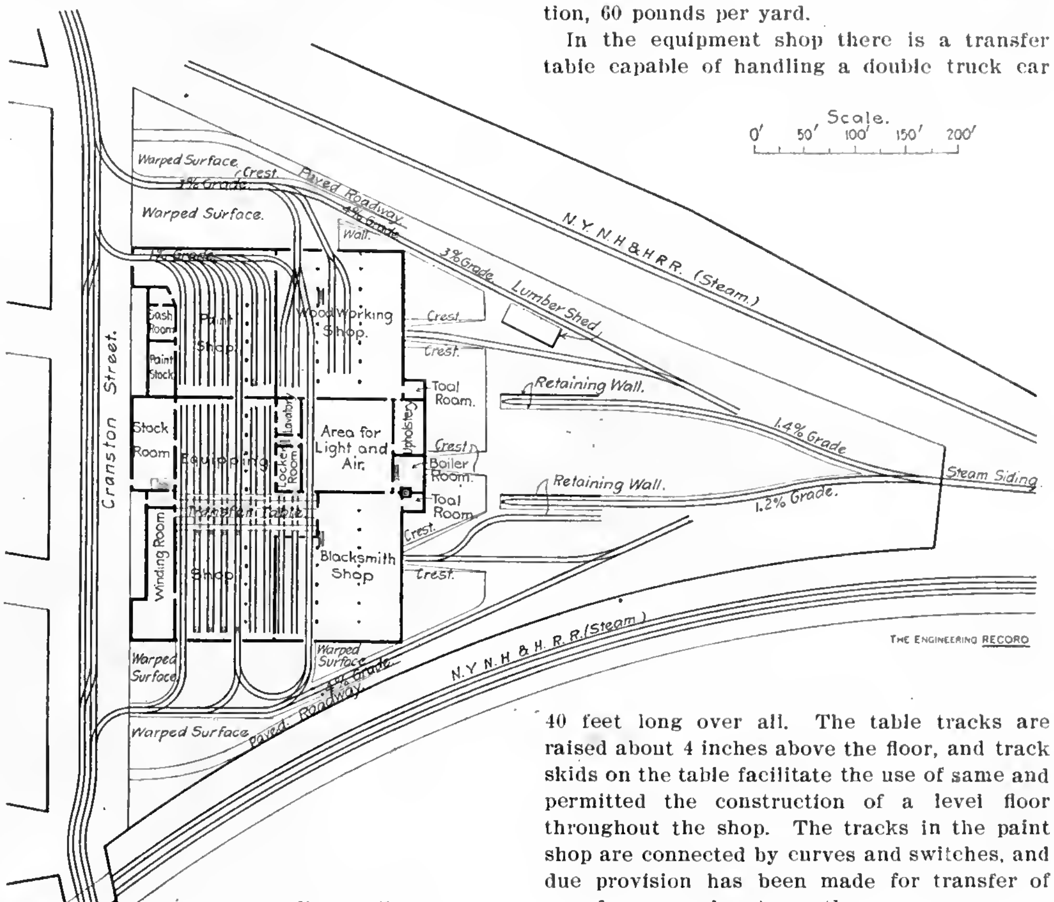
The test was perhaps more severe than could ever happen on a bridge, as the pavement would distribute the load more than the washers did, for in fact the iron washer crushed its way into the wood over an inch, so that the wood did not distribute the load. The iron pipe through the slab probably weakened it from the neutral axis downward.

As loads of five tons on one wheel are rare, this would give a factor of safety of between 5 and 6. All of the conditions of construction for this test can be duplicated in practice.

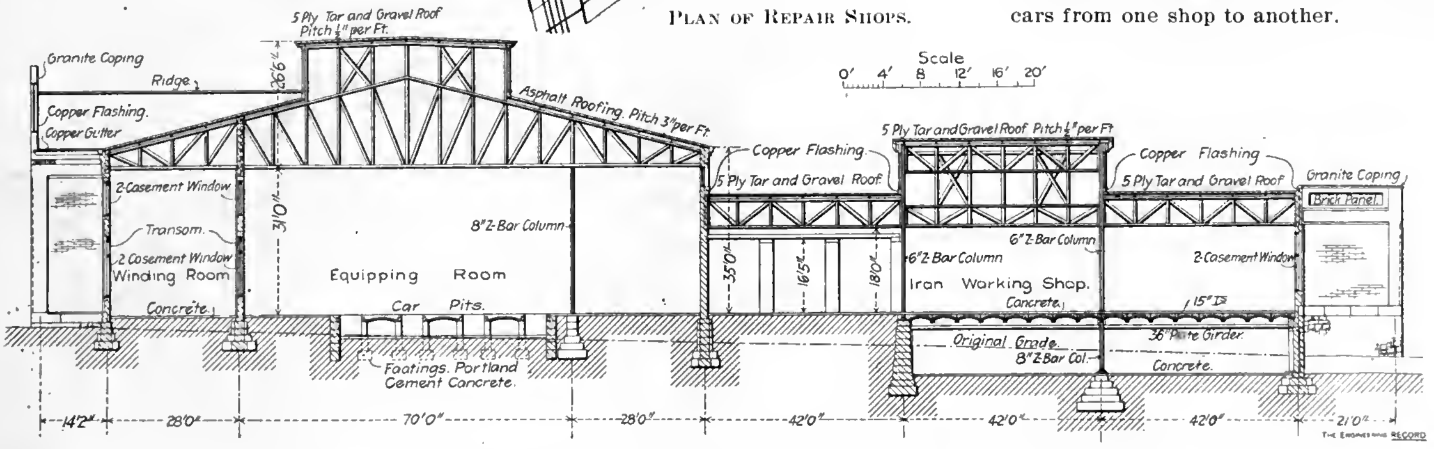
New Repair Shops of the Rhode Island Suburban Railway.

The accompanying cuts illustrate the arrangement of shops which were recently erected by the Rhode Island Suburban Railway Company at Providence, R. I. It is the purpose of the company to use these shops for repairs to the rolling stock of the street railway system of Providence and vicinity, which embraces the Union Railroad, the Pawtucket Street Railway and the Rhode Island Suburban Railway. This system includes about 270 miles of track, some 25 miles of which are on private right of way.

It will be readily understood that such a system is equipped with sufficient rolling stock to require large capacity in the repair department. The shops are located on a triangular lot between main and branch tracks of the New York, New Haven & Hartford Railroad. This advantageous situation has rendered it feasible to arrange for steam railroad sidings on the rear of the lot which has been laid out as a road department yard for the street railway company. Derricks have been provided for handling heavy material, and tracks have been run into the basements of the building for direct handling of smaller stock. Sufficient driveways have been provided for teams, and all parts of the shops are accessible to such traffic. All supplies can thus be conveniently received, and these facilities proved of great service during the construction of the building.



Plan of Repair Shops.



Cross-Section of the Repair Shops of the Rhode Island Suburban Railway.

The shops front on a suburban thoroughfare in a good residential section, and an effort has been made to develop a building which in the character of its contour and general lines would, with due regard to utility and economy, produce a structure at once expressive of its purpose and pleasing to the eye. This has been accomplished by more than the usual regard on the part of the engineers for the strictly architectural features of the structure. The building has a frontage of 390 feet along Cranston Street, which is 80 feet wide, and a general depth of 270 feet back from the street. The main portion along the street is of sufficient height to give the desired architectural effect, and is built without a basement. The rear wings are not so high and have a basement which is lighted by windows on two sides.

The shops include the following departments and are laid out so that there may be proper harmony in the relation of one department to another: equipping shop, winding room, machine shop, paint shop, paint stock room, wood working shop, general stock room, toilet room, locker room, tool room, sash room, office, and upholstery room.

The riveted steel roof trusses have been specially designed as to strength so that reasonable loads may be hung from them by means of chain hoists. This greatly facilitates the handling of heavy equipment and allows much flexibility in the arrangement of the shops. The floors are granolithic throughout, and the only wood used is in the roof planking, doors and windows. The shops have been in use by some of the departments for several months, and a noticeable result of this use is the excellence of the granolithic floors which appear to stand great abuse without damage. The car pits in the equipment shop and paint shop have brick walls on the exterior sides and brick piers between tracks. These piers support the tracks and intermediate platforms, but allow communication between the pits. The tracks in the shops are laid on concrete without cross ties, and consist of tee rails, Am. Soc. C. E. section, 60 pounds per yard.

In the equipment shop there is a transfer table capable of handling a double truck car 40 feet long over all. The table tracks are raised about 4 inches above the floor, and track skids on the table facilitate the use of same and permitted the construction of a level floor throughout the shop. The tracks in the paint shop are connected by curves and switches, and due provision has been made for transfer of cars from one shop to another.

The buildings are heated by the indirect hot blast system. Near the rear of the building is located a Bigelow-Manning vertical tubular boiler from which steam is conveyed through asbestos-covered piping to the heating chamber situated on the second floor over the toilet and locker rooms and practically in the center of the shops. Two fans of special design force the warmed air from the heater through galvanized piping to the various rooms of the shops. This piping varies in diameter from 5 feet near the chamber to 6 inches at the various outlets, which are usually located on the inside of the outer walls of the building about

7 feet above the floor level, each being provided with a hand damper. The outlets are placed about 12 feet apart so that the warm air is freely distributed through the rooms. The fan apparatus is in duplicate and the fans are operated by two motors constructed to run at varying speeds, which give at least four variations in the amount of hot air that may be supplied. The main ducts are located under the roofs of the building and are gauged to deliver the air at the outlets with practically a uniform velocity. The system has proved satisfactory, and during the cold weather of the past winter all of the shops have been kept at a suitable temperature. This system was designed and installed by Westinghouse, Church, Kerr & Company of New York.

The large number of windows on all sides of the building together with the monitors in the roof provide efficient illumination. The ceilings of the shops are equipped with a sprinkler system installed by the General Fire Extinguisher Company of Providence, and fire hydrants are located on three sides of the building a short distance away in the yard.

The general stock room is fitted with racks for a proper handling and storage of the various kinds of supplies. There is a second floor over the stock room and an office for other purposes. A second floor can also be put in over the winding room and other rooms on the front of the building if the capacity of the shops become inadequate. The shops have been equipped with modern machinery and tools and such of the machinery and tools from the company's old shops as were in good condition. The machines are belted to shafting driven by electric motors, the current for which is obtained from the main power station located in another part of the city. The shops are fitted with small traveling cranes and armature, car body and truck hoists located at various points.

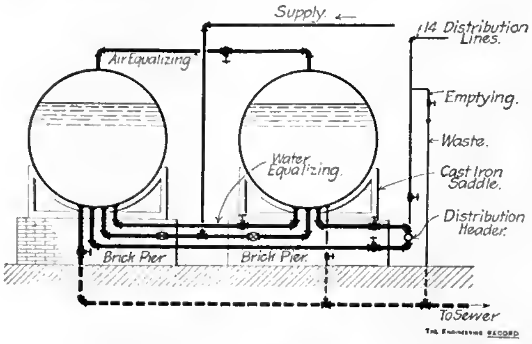
The shops have been equipped under the direction of Mr. W. D. Wright, the company's superintendent of equipment. Mr. Geo. B. Francis, M. Am. Soc. C. E., until recently chief engineer, devised and supervised the execution of the project, the drawings for which were prepared in his office under the direction of Mr. Joseph H. O'Brien, Assoc. M. Am. Soc. C. E., assistant engineer. The contractors for the building were Horton & Hemenway of Providence.

Plumbing in the Carnegie Residence, New York.

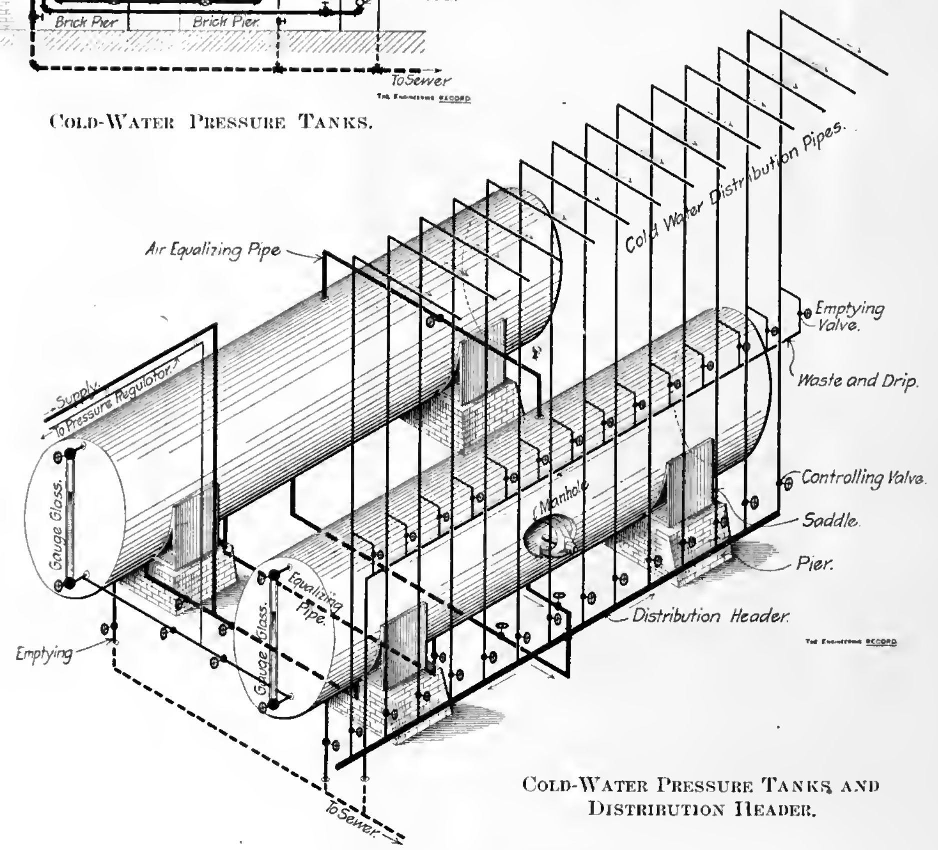
The new residence of Mr. Andrew Carnegie, on Fifth Avenue, between 90th and 91st Streets, New York, is a large four-story and basement building which occupies the entire west end of the block between the streets mentioned. A description of the general features of the water supply system and diagrams showing the arrangement of the pumps, tanks and filters and the location of the principal lines of water mains in the basement were published in The Engineering Record of July 5. These indicated the general arrangement and operation of the plant for the water supply and showed the connections to the pumps, tanks and filters in the conventional way indicated on the contract drawings. The piping is extensive and rather elaborate and great pains have been taken to arrange it neatly and symmetrically, and to make the connections with directness and simplicity. The valves have been grouped so far as possible close together so that they can be easily controlled, and are placed in order where their use and sequence is easily understood. The principal groups are for the pump and filter supplies, the cold-water distribution and the hot-water heating, supply and return, which are illustrated by the accompanying sketches, intended to supplement the general plans given in the previous article.

Provision is made for a very large daily consumption of water which is drawn from two separate street mains and is used for domestic purposes, fire service, steam boilers, hose washing, lawn sprinkling and spraying the trees and shrubbery in the extensive lawns and gardens. Water for domestic purposes and the steam heating boilers is filtered and distributed under a street pressure of about 20 pounds and under a direct pump pressure of 55 pounds. The former is intended to supply normally all fixtures below the second story and the latter to supply all fixtures above that level, but both are constructed with duplicate apparatus and cross-connected so as to be interchangeable and prevent any interruption of service through accident or alterations to any part of the plant.

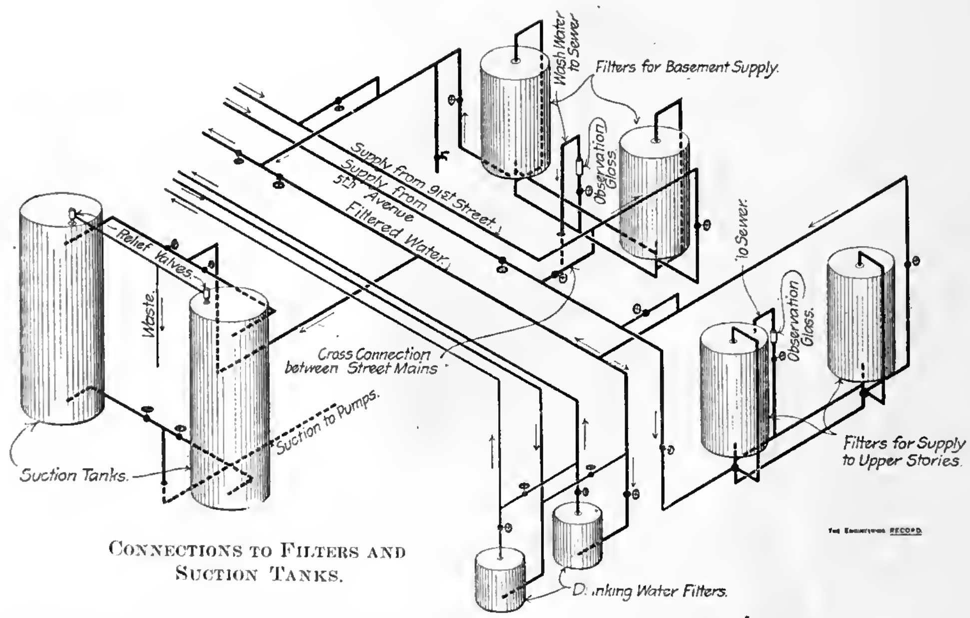
Branches for sill cock lines, hose connections and flush pipes for the fresh air inlets are taken from the street supplies inside the meters, beyond which they are run on the high basement ceiling to the filter room which has its depressed floor at the same level as that of the adjacent boiler and pump rooms, about 8 feet below that of the basement and 10 feet below the level of the street sewer. This gives a height of about 16 feet to the ceiling and affords ample headway for the pipes to run above the filters and the tall suction tanks. The room has no windows, is lighted by electric lamps and, having its walls faced with white glazed bricks and all the tanks coated with white enamel paint, presents a neat and airy appearance. The tanks and filters are arranged around the sides of the room and in a curved alcove as indicated in the general plan which accompanied the previous articles, and the center of the room is unobstructed except by the auxiliary hot air pump and furnace which is installed there. All the pipes are suspended by long rods from the steel ceiling beams, but at a sufficient height to provide ample head room beneath them, and are arranged in the same



Cold-Water Pressure Tanks.

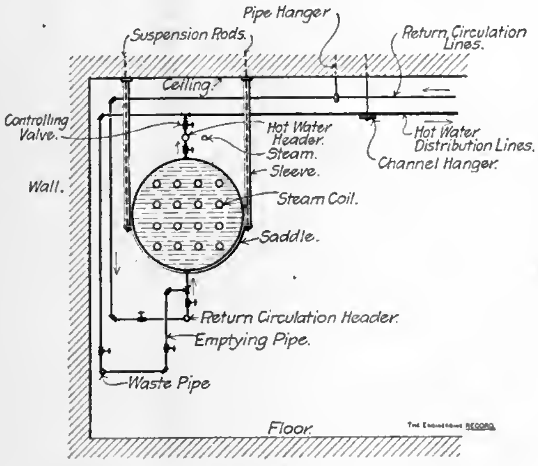


Cold-Water Pressure Tanks and Distribution Header.



Connections to Filters and Suction Tanks.

horizontal plane. All the supply and delivery pipes are brought in adjacent parallel lines to the center of the room, and thence that from the Fifth Avenue main is branched to the double filter intended to supply normally the street pressure system. Vertical inlet and outlet pipes are run down near the wall and connections made in the usual manner to the operating valve at the bottom of the filter. The filter for the pump pressure service is similarly connected and the supplies to both are cross-connected. The delivery pipes from both filters are cross-connected, and the one from the Fifth Avenue service is branched to a pipe with valved inlets to the tops of the two vertical 50-inch suction tanks, 12 feet high. The tanks have cross-con-

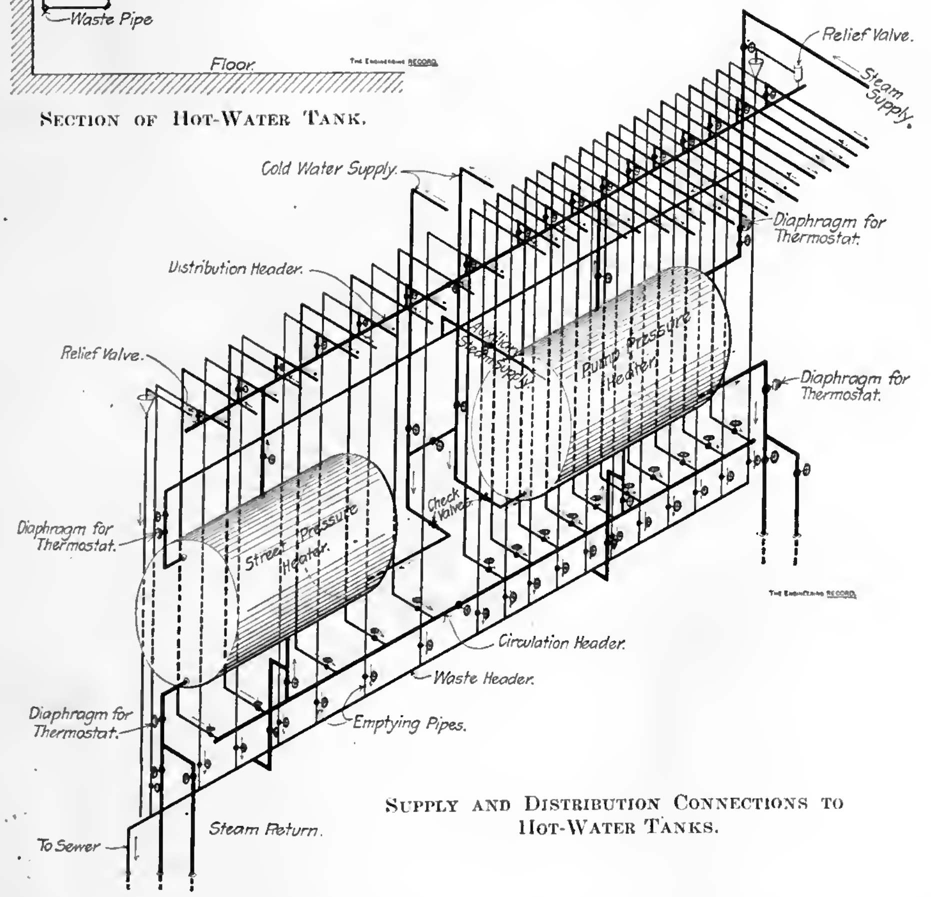


SECTION OF HOT-WATER TANK.

nected outlet pipes on the front side near the bottom from which a 4-inch suction main is carried under removable cast-iron floor plates to the pumps. On top of each tank there is set vertically a check valve with an inside ball-float connected to it in such a manner that if the water is pumped out faster than it enters from the filters it will fall and the opening of the valve will prevent the formation of a vacuum in the top of the tank.

The house pumps deliver directly to a pair of horizontal cylindrical pressure tanks seated in cast-iron saddles on brick piers on the basement floor. These tanks, like the suction tanks, were intended to be galvanized inside, but as this was found to be impracticable they were painted instead, and great difficulty was caused from the fumes of the paint, which could only escape through the manhole and were so suffocating that the men could remain inside only a short time at once. The pressure tanks are set low and are in the corner of the room so that it is necessary to have a special door through the wall on one side to give access to the manhole in the outside tank.

The principal connections are made with vertical pipes screwed into the cylindrical shell, and all of them are on the under side on the center line except those for the air-equalizing pipe, which are on top. The inlets and the emptying pipes are near the front ends of the tanks, and the water equalizing pipe and the outlets are near the middle points. The outlet pipes are connected with a double T to the 4-inch header, made up of T's and nipples. It is set horizontally near the floor, and from it the distribution lines are run vertically to the ceiling and thence taken to the feet of the riser lines for the different groups of fixtures. The two tanks are intended to operate together and all their principal valves are normally open but can be closed so as to cut out either tank and maintain complete service with the other one. It is intended to have the upper parts of the tanks always filled with air to provide an expansion cushion and prevent water hammer, and gauge glasses nearly 60 inches high are provided to show the water level. The



SUPPLY AND DISTRIBUTION CONNECTIONS TO HOT-WATER TANKS.

bottom inlets of the gauge glasses are connected by a horizontal cross pipe from which a small pressure pipe is run to a regulator, which automatically controls the operation of the pumps so as to maintain a constant pressure of about 55 pounds in the tanks and throughout the distribution system. A supply of compressed air in the tops of the tanks is provided by Quimby electric pumps which are valved to inject a portion of air with the regular water supply. If too much air accumulates in the tanks it can be drawn off through pet cocks not shown in the diagram, and the pump can be arranged so as to deliver less air with the water.

The tinned copper hot-water tanks are suspended from the ceiling beams, as indicated in the sketch, by vertical screw rods with pipe sleeves against which the flanges of the saddle bands are screwed up tight so as to hold them rigidly in place. This secures the tanks vertically, and the connections of short stiff pipes, which are screwed into the reinforced shells, brace them firmly in transverse and longitudinal directions. During the winter steam for the interior brass coils is supplied from the main boilers installed for the radiator system. In summer these boilers will not be in service and an independent small boiler enclosed in a setting of fire bricks faced with glazed white bricks is provided to operate the domestic hot-water system. Both steam supplies are connected to a horizontal longitudinal pipe over the tanks and are controlled by Johnson thermostats having valves operated by pneumatic diaphragms with air compressed by a special electric pump arranged to be started and stopped automatically by the variations of pressure in the receiver.

There is a vertical outlet from the upper side of each tank which is connected to the distribution header. A gate valve in the center of the header separates the street and pump pressure tanks, but may be opened to put both under the same pressure if necessary. Seven short vertical pipes are connected to the street pressure end of the header and ten to the pump pressure end, and at the ceiling all terminate in T's with a pipe in one direction to the foot of the riser line and one in the opposite direction, which is carried down the face of the adjacent wall and is valved to a waste pipe to provide for the emptying of any line without interfering with any other line. Safety valves are set at the ends of the header to discharge any steam or excess pressure, and have drip pipes terminating over funnels connected to the same waste pipe, which is trapped below the floor and discharges into an open sink.

Return circulation pipes from above the highest fixtures on the different lines are run between and parallel to the supply pipes on the basement ceiling; they are carried down the face of the wall with the waste pipes and are branched horizontally to enter the return circulation header under the tanks, near which they are valved so as to enable the lines to be cut out for repairs. The return header, like the supply header, has a middle gate valve dividing it into pump and street pressure ends corresponding to the tanks and connected with them by the upper ends of emptying pipes which are valved into the waste pipe.

The large number of parallel pipes suspended from the ceiling are symmetrically arranged with unions, valves, T's, etc., in straight lines and present an attractive appearance. Where they turn at right angles to go to opposite sides of the house the angles have their vertices in the same diagonal line, giving the effect of a regular miter joint which is very workmanlike. Some of the pipes are supported on simple cross-bars made of a length of horizontal pipe with vertical hangers reaching to the upper side of the ceiling beams and supported from them with cross pieces through T's at their upper ends. In other cases the horizontal pipes are over instead of under the supported lines and have ordinary double yoke standards screwed into them and engaging the pipes. In many cases the pipes are screwed down on top of narrow boards laid between the flanges of a 4-inch horizontal channel web down, which is suspended from the ceiling by vertical screw rods through the ends. Care is taken to provide efficient support for all pipe lines. All water pipes are carried from the ceiling and sewer pipes are carried from the ceiling or are supported on piers of white enameled brick built up from the cellar floor 10 feet apart.

All fixtures in the house have their exposed piping, traps, valves and all other metal work made of white metal, which is also used for the legs and corners of sinks and wash stands, for floor strainers, escutcheon plates, towel racks, brackets, etc. In the basement and in the servants' rooms in the fourth floor the white metal is polished and is not plated; elsewhere it is silver plated. All sinks, even for the refrigerator wastes and tell-tales in the basement, are made of porcelain. In the scullery and kitchen there are extra large sinks with white marble wall slabs above them and large white marble countersunk floor slabs. The two scullery sinks are set 5 feet apart and the space between them and at each end is covered by drip boards hinged to fold up vertically against the wall. Each sink has a large Tucker grease trap and is provided with hot, cold and drinking water.

A handsome 12x20-foot bathroom is provided in the basement for the engineer. It has mosaic floor and white marble wainscot 8 feet high and all trim and mouldings are of white marble to the exclusion of all woodwork, except for the doors. At one end three wash basins are set in a long white marble slab, with a plate glass mirror in the wall above it. In the opposite end of the room there are two water closets with white marble partitions and three-quarter length screen doors of dark polished oak with dull bronze locks and hinges. Adjacent to the water closets white marble partition slabs as high as the wainscot enclose a porcelain bath tub with a shower and a duck curtain on a rod. The bathroom has a full length solid oak door glazed with frosted glass.

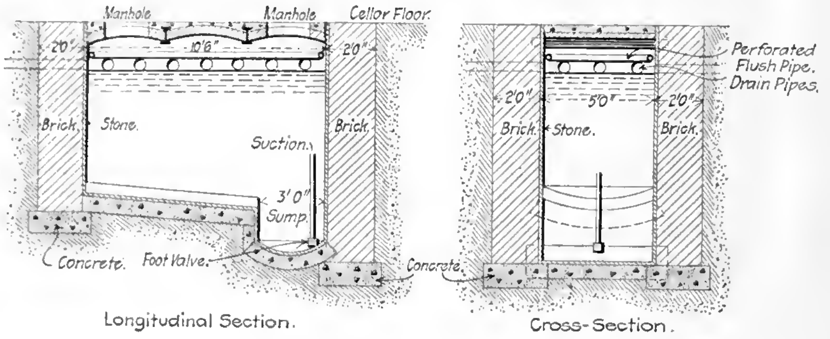
The boudoir bathroom is about 20 feet square with a white marble floor in parquetry pattern and white marble wainscot 6 feet high. The upper part of the walls is finished in white and the large windows and wall mirrors combine to give a very bright and airy appearance not often found in such rooms. There is a porcelain bath tub and sitz bath and two wash basins with separate tables, one of them being fitted with a swinging shampoo shower which has supply pipes rising from the tops of the hot and cold water faucets. In one corner of the room a separate enclosure extends to the ceiling for the water closet.

The owner's bath room is similar, but somewhat smaller, and has only one wash basin; all the guests' bathrooms have the water closets enclosed by walls reaching to the ceiling and forming separate inner rooms. One of the guests' toilet rooms is provided with a white metal large size needle bath with shower and liver sprays which is set in an alcove with white marble partition slabs and shallow floor basin and is screened in front by a white duck curtain. There is a third family bathroom, and a special bathroom and kitchen or pantry for the nursery, and there is a small bathroom for the seamstress. This room is limited in size by the pipe shaft and only contains a 4-foot tub, a wash basin and a water closet without enclosing partition, but the character of the fixtures and their quality correspond with the others described. All bath tubs are provided with 3-inch overflows and wastes which are tested to insure their capacity to discharge the water faster than it can be received through both faucets full open under maximum pressure. In the fourth story there is one bathroom for the women servants and another for the men servants. Each has two wash basins in a white marble slab, with a marble back and countersunk floor slab. There are two water closets and a bath tub enclosed with 6-foot white marble partition slabs with oak doors, and in the women's room there is a slop sink. In most cases the slop sinks are in separate closets and all are supplied with drinking water which is delivered through a special faucet attached to and just above the long braced spout for the hot and cold water to the sink and for filling pails, etc. In the butler's pantry and nursery pantry there are large single and double sinks which, with their tables, are lined and covered with copper, silver plated, and are supplied with hot and cold water and drinking water through high goose-neck swing faucets.

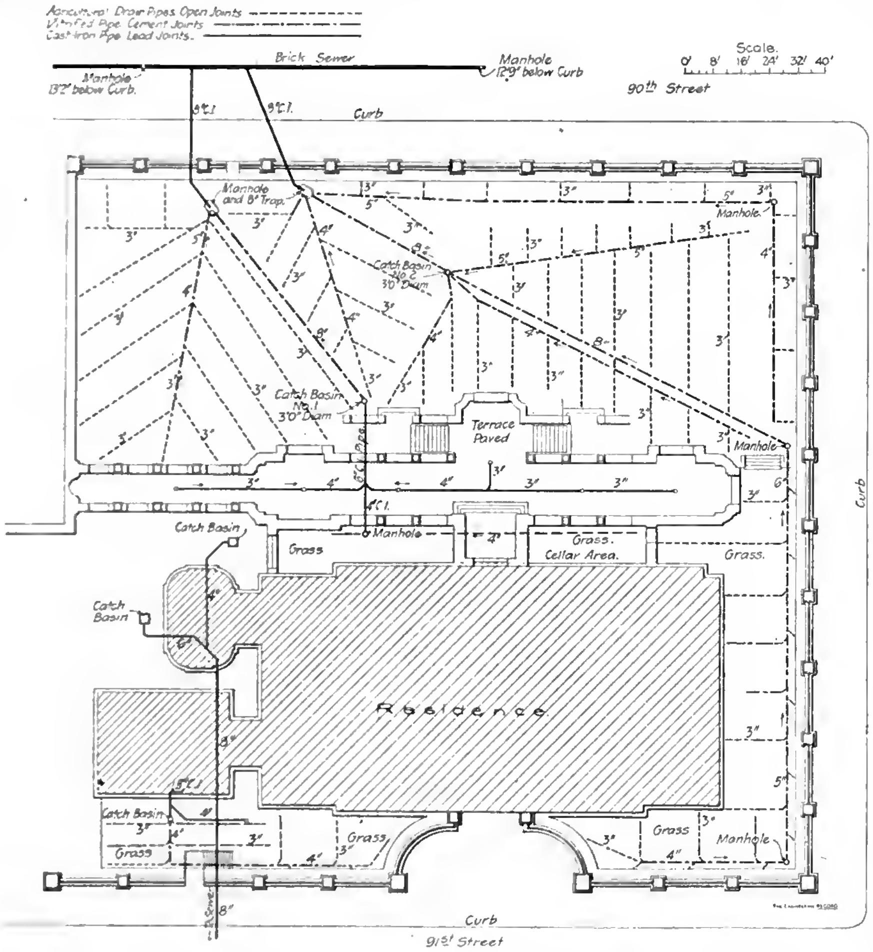
The storm water from the cellar areas around the building, the wastes from the engineer's and drip sinks, the emptying pipes from the hot water, suction and pressure tanks, the drips from the relief valves and the drainage from the floor strainers are connected in one 5-inch, four 4-inch, two 3-inch and one 2-inch cast-iron pipes under the cellar floor and drained into a tank under the pump room floor and about 10 feet below the level of the street sewer. It is 4 feet wide, 6 feet deep and 12 feet long with a 1½-foot sump at one end. It has 12-inch brick walls and a concrete bottom surfaced with bricks set edgeways. It is lined with Alberene stone slabs 1 inch thick, and is covered with flat brick arches supported by I-beams 4 feet apart. It has two 24-inch cast-iron manhole covers and a 1-inch perforated brass pipe for washing down the walls.

The tank is automatically emptied by two improved centrifugal pumps made by the Lawrence Machine Company. They are specially made of bronze or composition metal and have a capacity of 100 gallons each per minute. Each pump has a 3-horse-power direct-coupled electric motor on the same bed plate and is guaranteed to work noiselessly. The pumps are controlled by tinned copper ball floats operating electric switches which start or stop them when the tank is full or empty. The 3-inch suction pipes are provided with continuous service foot valves and steam primers. The 3-inch discharge pipes are trapped into the 4-inch sewer pipe at the boiler room ceiling. The suction pipes have gate valves which may be closed to allow the pumps to empty the blow-off tank.

Special provision was made for the subsoil drainage of the site of the house and the adjacent grounds. The cellar excavation and excavations under the moat and gardens were filled 1 foot deep with broken stone, in which 3 and 4-inch lines of unglazed agricultural drain pipes were laid with open joints. These lines are connected with Y-branches in lines of vitrified sewer pipes with cemented joints



Drainage Tank under Boiler Room.



Sub-Soil Drainage for Gardens and Moats.

which in turn discharge into cast-iron pipes with lead joints, which are run to the street sewers. After the pipes were laid the area outside the house was backfilled with selected earth and the moats, terraces and gardens were constructed.

Messrs. Babb, Cook & Willard are the architects and Mr. William Paul Gerhard is the hydraulic and sanitary engineer of this residence and grounds. Mr. James Armstrong is the contractor for the plumbing and Mr. Charles T. Wills is the contractor for the sub-surface drainage system.

The Economic Need of Technical Education.

Extracts from a paper by Victor C. Alderson, Dean of Armour Institute of Technology in the "Journal" of the Western Society of Engineers.

Most, if not all, recent improvements in educational methods in this country have been purely academic or philosophic; they have been evolved by musing in the library, or perhaps from class-room experience; but none of them have resulted from a close acquaintance with the real conditions of the industrial and business warfare into which the student enters when he leaves the school. The so-called "systematical development" given to young people is but a twentieth-century way of training a "jack-of-all-trades." The one thing needful will not come from teachers' conferences, nor county institutes, nor the august meetings of school superintendents, for the attendants at these assemblages have not, and cannot get from their experience, the proper point of view. Educators of to-day should break out of the circle in which they are traveling and look at matters from a new point of view. This should be from the vantage ground of the factory, the workshop, the railroad or the counting-room; it should be industrial and commercial rather than academic. The practical needs of every-day workers should be considered, after a scientific study of conditions at present existing.

With advancing civilization, with the luxuries of yesterday becoming conveniences to-day and necessities to-morrow, with our products going to far-away lands in competition with local goods, with competition becoming sharper day by day, with the margin of profit becoming steadily narrower, it is found necessary to seek new lines of economy. In the accurate application of the laws of science, an almost limitless field is open. Mere practice, no matter how long continued, cannot long avail against theory followed by intelligent application. A stupid fireman can burn up the profits of his establishment by ignorant firing; an engineman was recently discovered running an engine for no other purpose than to get exhaust steam to heat his building. He was a "practical man of long experience." A soap manufacturer who had depended upon the "knack" of one workman for many years nearly went into bankruptcy when the man died, for no one else seemed to have the requisite "knack"; but the employment of a trained chemist without the "knack" regained for him his lost business. A large railroad company recently saved more than half a million dollars in six months by equipping a laboratory in connection with its machine shops and putting in charge a technically trained man—one who could unite theory with common sense. The present age has truly been called the age of science, but with this designation the story is only half told. Pure science to be of the greatest value must be applied. The application of science to industry has made this the age of technical education; it has changed many of the conditions of life and has given rise to new problems, the solution of which depends in a high degree upon men who have received a technical education. A dozen years ago the introduction of manual training was always preceded by a spirited controversy; to-day its value is generally conceded and its introduction is becoming fairly common. Not only is it incorporated into the high school curriculum, but it is fast going where it especially belongs—into the graded schools, as an organic part of educational training. In another dozen years the necessity for advocating manual training will probably have ceased. What new features will be advanced to take its place? What new element in educational progress will be demanding recognition? In all probability it will be secondary technical education. Leaving out of consideration the two extremes—unskilled labor at the foot of the educational ladder and those professions at the top which demand a preliminary college training—there are many vocations in the middle ground for which a technical training is necessary. This broad field has been cultivated very little in this country. England, France, Holland, Belgium, Germany, Austria and Switzerland have all done more than we have, and it may not come amiss to examine the system of technical education in one of these countries.

Switzerland is best known to Americans as a region of mountain scenery, but it is an object lesson for us in a manner not yet fully recognized. The natural conditions under which the Swiss people have struggled for the past six hundred years have been so burdensome and their industrial success so pronounced, that Switzerland is to-day the best of the European countries in which to study the close relation which exists between the technical education of the masses of the people and national industrial prosperity.

Like the United States, Switzerland has no national school system. The constitution of the federation allows the Federal Government to establish a polytechnicum, a federal university and other institutions of higher instruction or to subsidize such local schools as may be selected. Provision for elementary instruction must be made by the several cantons, but the Federal Government in most cases subsidizes these cantonal schools. There is no Federal university, but six cantonal universities exist at Basel (founded in 1460), Zurich (1835), Berne (1834), Geneva (1873), Fribourg (1889), and Lausanne (1891). The polytechnicum at Zurich (founded in 1854) is supported entirely by the Federal Government. The school covers the higher scientific and technical fields in a most thorough manner. For accuracy of instruction, completeness of equipment, and high professional standard, it is the peer of any technical school in Europe. With a most complete cement-testing laboratory; a mechanical laboratory covering every possible demand that can be made upon it; with a department of electricity equipped regardless of expense; with extensive departments of chemistry, forestry and agriculture; with a new department devoted to the testing of building material alone, it is evident that the Federal Government has provided liberally for the most advanced instruction in technical lines. There seems to be no fear in the minds of the Swiss that a man can be too scientific, or that too deep a study of the scientific basis of industrial questions is possible.

Next below the Zurich Polytechnicum are three technica, or technical schools, offering less theory and more practice, and relating their work more closely to the trades and industries. One is located at Bienne; the second, at Winterthur, is noted all over Europe for the thoroughness of its instruction and the success of its graduates; the third is at Burgdorf, where Pestalozzi taught his first school and where Frœbel at one time was developing his philosophy of education. This group of technical schools gives scientific character to the entire Swiss system of technical education.

The trade and industrial schools—to be carefully distinguished from the group first described—have been established to teach the homely trades, and are a conspicuous feature in the educational and industrial life of Switzerland. They are found in every canton, and are intended to make the local industries more successful.

Swiss education is the result of no single philosophy, no one method, no selfish utilitarian object; it has not been dominated by social reformers nor by mere theorists; it is a composite type, the result of many conflicting views and necessities. Throughout the entire system can be seen, however, an attempt to solve the problem of the relation between education and industrial prosperity. This point of view is the one thing needful in developing our own system of technical education, and the one idea which we can best borrow from the Swiss. With them no valuable feature—either cultural or technical—is ignored. Each branch of knowledge is prized according to its value as discipline or as a distinct aid in professional or industrial pursuits. Their object is not only to train men and women for their vocations, but to build up new industries or at least to extend and strengthen those already established.

Technical education in this country is a product of the last quarter of a century. The first legislation which gave a decided impetus to this form of education for the American youth was the Morrill Land Grant Act of 1862. This act granted public land to the several States, apportioning 30,000 acres for each Senator and Representative, to be devoted solely to the advancement of instruction in the agricultural and mechanic arts. The full effect of this act was not felt until after the beginning of the last quarter of the century, when there was established in almost every State a school to carry out the purpose of the act. From that time on the growth of technological education was remarkable, whether we consider the actual outlay upon material equipment, the increased number of students, the constantly improved methods of instruction or the continued elevation of the standard of instruction. This great advance came from a general acceptance of the view that industry needed the aid and assistance which comes from technical training. With this change of industrial demands came the needed supply in the form of young men trained, not in the classic halls of some favored university, but in the workshops and the laboratories of institutes of technology. These men are educated to understand the fundamental principles of science not merely in their broad, general aspect, but in every matter of practice, detail and application. They supply, to only a limited extent, however, the needs of modern industry, since they furnish merely the highest grade of workers, as does the Zurich Polytechnicum and the technica at Winterthur, Bienne and Burgdorf. They furnish a technical training not for the many, but only for the few. What should be done for the great army of workers in our industries, who need at once the skill of the mechanic, together with sufficient intelligence and training to understand the directions of the professional engineers above them? Their number is legion. At the present time this country makes little or no adequate provision for their instruction. This is the realm of secondary education.

In considering so radical a measure some important features should be emphasized in order to avoid misapprehension. The main idea in such a plan would be to take a boy just graduating from the grammar school and give him a good secondary education, together with a training on one or more technical or trade lines. Such a scheme would be unsuccessful if the school were to be maintained on the usual high school lines of to-day; it would necessitate a highly elastic or elective plan of operation, because no individual could successfully study all the subjects offered. The routine courses in physics, chemistry, mathematics and drawing would necessarily be much shortened; but every progressive teacher knows that much of these subjects, as at present taught, is of little value in strictly technical pursuits. Much of the laboratory, drafting-room and testing work now done by the technical colleges could be incorporated into the courses, and we should have technical high schools as real "people's colleges." There can be no reasonable doubt that our technical education in the United States is weakest in this spot.

In our high-grade institutes of technology we are training the commissioned officers of our industrial army, but the great mass of non-commissioned officers and privates are left uncared for. As indicated in the report of the Carnegie committee, technical education may be said to run parallel with the general lines of education, and be divided into three parts, corresponding to the grammar, high school and college grades of the established system. The lowest grade is generally picked up in the shop by boys without special training, who have had merely a grammar school education. It is represented in Switzerland by the Sunday, holiday and evening schools for artisans. It develops the "practical man." The highest grade is represented by the polytechnicum and technica in Switzerland and by technical colleges and institutes of technology in this country. These represent the phase of technical education that demands thorough knowledge of mathematics and the sciences, and is distinctly professional in character. Between these two extremes lies the region of secondary technical education which is represented in Switzerland by the trade school and the specialized technical school. In the United States it is represented by more or less feeble efforts in a few trade schools, in a limited number of private institutions aimed to help the workingmen, and in night schools. Besides these instrumentalities there is another, arisen only within the past few years, which for pure bigness eclipses all other efforts—the schools of correspondence. While our educators have been discussing mere theories and methods and have been building a Chinese wall about their so-called superb school systems, shutting out all who were too large to walk through the narrow gateways which they themselves had made, private enterprise has discovered that half a million young Americans outside the walls were hungry for a technical education. When the history of education shall have been written, no greater reproach will rest upon the educators of this decade than their failure to hear the call of this multitude for an education suited to their needs. If the farmer's son can secure at the State university free instruction in scientific agriculture, what good reason is there for depriving the son of a mechanic from securing free instruction in engineering practice, machine tool work, or any other industrial calling, at the city technical high school? We should follow the example of Switzerland and, recognizing the dependence of national prosperity upon technical education, set about the task of providing an education for all classes of workers suited to their lives. The technical high school, if properly equipped and put in close relationship with the trades and industries, will satisfy this national need; it will not be a copy of the European trade school, but rather an adaptation of the trade school which will be in harmony with American thought and American educational ideals.

Industrial warfare is not a new idea, but its sociological effect in giving impetus to technical education during recent years is noteworthy. We are familiar with martial warfare. Our newspapers for the past few years have been teeming with reports of battles, of warfare, of disease and death as the concomitants of war. But in the midst of all this clamor there has been going on—largely unknown and unnoticed—the most bitter, the most relentless war in the history of the world; a war not for territory, not for naval nor military glory, but for wealth, for industrial supremacy—a contest of brain with brain, skill with skill, economy with economy, technical training with technical training. It is only another example of the "struggle for existence." The war in South Africa or the Philippines is less fatal to the workingman than the ceaseless competition of similar workingmen in other countries. It is this unremitting rivalry between workers of the same class the world over that makes the cultivation of the workingman's powers by means of technical education an absolute necessity. That nation that neglects to equip its workmen with the armament of industry—technical education—will surely be defeated and become a decaying nation. These workers should receive immediate and thoughtful attention, for they are the bone and sinew of successful national and industrial life. That they should be technically trained through the medium of the technical high school is at the present time the greatest economic need of the American people.

Trade Publications.

The DeMan system of fireproof construction has a number of special features of which the most generally interesting is a concrete beam system with a reinforcement of steel bars. The cross-section of the metal varies with the loading and design of beam or floor, but the bars are always given twists every 2 to 4 inches which form shoulders that anchor the strips in the concrete. Full descriptions of this and other features of the system, tables for computing the strength of the work, and illustrations of buildings where it has been employed are given in an 80-page book published by the American Fireproofing & Cement Construction Co., 1135 Broadway, New York. The company has also prepared a catalogue illustrating in colors a variety of tiles about 8 ins. square and 1 in. thick used for floors in buildings, private sidewalks and like situations.

A beautifully printed book entitled "How Best to Heat Our Homes" has been issued by the Gurney Heater Mfg. Co., Boston. It describes the general features of steam and hot water heating, and explains the general construction of the company's warming apparatus.

A type of reinforced concrete flooring has been introduced by W. N. Wight & Co., 160 Fifth Ave., New York. It is called the lock-woven system from the high-carbon steel fabric forming the reinforcement of the concrete, described in a circular recently prepared by the firm.

A paint called "Galvanum" has been prepared particularly for covering galvanized iron and steel. It is made in two shades only, dark lead and stone drab, but can be given another coat of any desired color. The makers, the Goheen Mfg. Co., Canton, O., have issued a pamphlet giving references to a number of large users of it.

A system of piling recently introduced in the Middle States is constructed by placing a steel core inside a tapered sheet iron shell and driving this like a wooden pile. The core is then withdrawn and the shell filled with concrete, steel rods being embedded in the concrete if lateral strength is desired. The system is described in a pamphlet issued by the Raymond Concrete Pile Co., Merchants' Loan & Trust Bldg., Chicago.

The Coffin Valve Co., Neponset; Boston, Mass., has prepared a useful illustrated folder concerning standard foot valves from 6 to 48 inches in size.

A successful test of a garbage cremator for use in private and public buildings was recently made in New York under the direction of Mr. Morgan J. Cragin, 285 East 43d St., Chicago. The device has a coal grate under a water-tube grate on which the garbage is incinerated. The tube grate is used as a water heater if desired. The apparatus is fully described in a pamphlet published by Mr. Cragin, which also gives a list of many Chicago buildings where it is used.

An automatic circuit-breaker has been designed by the Westinghouse Electric & Mfg. Co. for use in charging automobile storage batteries. Its purpose is to protect the battery automatically against overcharging, and its construction and use are explained in an illustrated circular which every user of an electric automobile will find of interest.

Several months ago Dr. F. A. C. Perrine, president of the Stanley Electric Mfg. Co., read an interesting general paper on the power plants of the Pacific Coast before the New York Electric Society. It has recently been published in an elaborately illustrated pamphlet which will prove valuable to all who desire to become acquainted with the notable plants of that section. Copies can be obtained from Ray D. Lillibridge, 170 Broadway, New York.

A catalogue of drawing instruments, paper, inks, surveying instruments and similar supplies has been issued by Williams, Brown & Earle, 918 Chestnut St., Philadelphia. Special attention is paid to transparent cloths and special drawing boards.

A pamphlet has been issued by the American Air-Compressor Works, 26 Cortlandt St., New York, describing the general features of its steam and power compressors, vacuum pumps, receivers and air-lift plants. Tables of sizes are given and rules for setting up compressors.

A 52-page album of excellent views of concrete structures with a reinforcement of twisted steel rods has been published by the Aberthaw Construction Co., 8 Beacon St., Boston. The illustrations show bridges, buildings, power plants and industrial plants built wholly or in part of reinforced concrete, a number of the structures being already familiar to the readers of this journal, such as the buildings of the Pacific Coast Borax Co., the Paterson Edison Illuminating Co. and the Central Lard Co., the Nassau County Courthouse, the St. James Church in Brooklyn, and a large Philadelphia sewer.

Mr. Edward M. Hagar, manager of the cement department of the Illinois Steel Co., Chicago, has reprinted in handy form the report of the Board of Engineer Officers, U. S. A., on Testing Hydraulic Cements, which was published some months ago. This is one of the most important American documents on the subject and gives specifications as well as directions for testing.

An album of large engravings of views along the New York Rapid Transit R. R., with an excellent description of the way construction is carried on, has been published by the Rand Drill Co., New York. It is easily the best concise description of the work yet made public, and the illustrations merit the term sumptuous.

The Stanley Electric Mfg. Co., Pittsfield, Mass., has issued a complete illustrated catalogue of the types of switches it makes, from the simplest small knife switch to the large 60,000-volt combined switch and fuse or the combined oil switch and circuit-breaker. This pamphlet appears as No. 127 in the company's series of bulletins.

The Riehlé Bros. Testing Machine Co., 1424 North 9th St., Philadelphia, has issued a large catalogue of the many varieties of testing apparatus it makes. The requirements of purchasers of many classes of material call for tests of some sort, and the machines made for the purpose have reached a degree of specialization that is surprising, as this book will conclusively prove.

Personal Notes.

Mr. J. R. C. Brown has been elected city engineer of Ironton, O., to succeed Mr. F. G. Leete, resigned.

City Engineer McDonald, of Anaconda, Mont., has resigned to accept a position in the School of Mines, in Butte.

The Lauer & Harper Co., engineers and contractors for steel buildings and bridges and heavy timber construction, have moved from Baltimore into their office and works at Westport, Md.

Mr. Charles H. Ledlie, M. Am. Soc. C. E., whose association with the New Orleans Railways Co., of New Orleans, was mentioned in this column April 12, is first vice-president. Mr. Alexander Black is announced as chief engineer and head of the electrical department, and Mr. E. B. McKinney, superintendent of power houses.

Major George McC. Derby, Corps of Engineers, U. S. A., has been ordered to Louisville, to relieve Major Ernest H. Ruffner, and his duties in connection with the fourth district of the Mississippi River improvement, at New Orleans, are to be assumed by Capt. Charles S. Bromwell, who has been detached from the office of the Chief of Engineers for that purpose. Lieut. W. J. Barden, for some time city engineer of Havana and only recently back from that post, has been assigned to duty at the Engineer School of Application, Washington Barracks.

A Water-Power Plant that will include a 10x10-foot tunnel, 440 feet long, driven at an inclination of 14½ degrees is now being developed near Shoshone, Idaho, on the Snake River. The tunnel, of which 240 feet has been driven, will tap the Bridal Veil Fall and will provide a head of 190 feet. According to Mr. J. V. Blow, the superintendent of the plant, a total of 5,000 to 7,000 horse-power is to be first installed, and when it is desired to increase the production, a second tunnel will be driven.

Drafts in Schoolrooms in Detroit, caused by the air passing along the floors to the vent flues, are to be overcome, if possible, by running one or two rows of steam pipes under the windows, according to Mr. Ralph Collamore, in "The Technic," of the University of Michigan. Whenever possible, several vent openings are provided, usually by taking off about 6 inches from the bottoms of the doors opening to the cloak rooms, the vent flue proper leading from these rooms. The schoolrooms are warmed by the fresh warm air supply, five-eighths of the total heating surface in the heating coils and three-eighths in the tempering coils.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xvi, xviii and xxvii.

WATER.

Mt. Gilead, O.—Engr. J. B. Weddell, of Mansfield, O., writes that contracts for constructing a water works system for the Mt. Gilead Water, Light & Power Co. (bids opened July 23) have been awarded as follows: Pipe for the 5 miles of line, 2,000 ft. 8-in., 46 tons; 12,000 ft. 6-in., 200 tons, and 12,000 ft. 4-in., 150 tons, to the Massillon Iron & Steel Co., Massillon, O., at $32 per ton; pipe laying, to J. M. Healy, of Chicago, Ill., total for labor and material, $18,000; valves, 32, and hydrants, 48, to Darling Pump Co., Williamsport, Pa., for $1,350; tower, 50,000-gal. capacity, 129 ft. high, to Chicago Bridge & Iron Co., of Chicago, for $4,125. Contract for pump was not awarded.

Cheyenne, Wyo.—Bids will be received by the City Clk., E. A. Abry, until Aug. 21 for constructing a masonry dam on the Middle Fork of Crow Creek.
Bids are wanted Aug. 14 for furnishing 8,000 bbls. of Portland cement, to be used in the construction of masonry dam.

Columbus, Ind.—Bids are wanted Aug. 7 for the construction of a new water works pump of 5,000,000-gal. capacity. Jas. Cochrane, City Clk.

Baldwins, L. I., N. Y.—Bids are wanted Aug. 8 (readvertisement) for furnishing, constructing and erecting a pumping plant, with all appurtenances complete at Millburn Engine House. Address Robt. Grier Monroe, Comr. Dept. of Water Supply, Gas & Electricity, New York City.

Henry, Ill.—Bids are wanted Aug. 10 (extension of date) for a system of water works, including 1,050 ft. of 8-in., 2,940 ft. 6-in. and 25,000 ft. of 4-in. pipe, with specials, hydrants, gate valves, etc. A. G. Humphrey, Mayor.

New York, N. Y.—Bids are wanted Aug. 7 for furnishing, delivering and laying water mains in numerous streets in the Boro. of Bronx; time for the completion of contract, 300 days; amount of security required, $50,000. Robt. Grier Monroe, Comr. Dept. of Water Supply, Gas & Electricity.

South Bend, Ind.—City Engr. A. J. Hammond writes that the city will extend the water mains, requiring about one mile of 12-in. cast iron pipe. M. L. Rogers, Supt. of Water Works.

Evansville, Minn.—Village Clk. S. L. Burton writes the contract for constructing water works has been awarded to W. D. Lovell, of Des Moines, for $6,402.

Anadarko, Okla. Ter.—City Clk. F. V. Hamilton writes that the contract for preliminary surveys, with plans for a system of water works, has been awarded to Burns & McDonnell, of Kansas City, Mo. Estimated cost of system, $40,000.

Chinook, Mont.—Town Clk. M. F. Marsh writes that at the recent election bonds to the amount of $24,000 were voted for water works.

North Yakima, Wash.—Chester A. Congdon, of Duluth, writes that the Yakima Valley Canal Co. proposes to extend the Congdon Canal, at a probable cost of $35,000. Work to be done by day's work. Alfred Bannister, Engr. in Charge.

Revelstoke, B. C.—Engr. Henry B. Smith, of Rossland, B. C., writes that a survey with report and estimate has been made for water works, and these are now under consideration of the Council.

Dallas, Tex.—The City Council has adopted a report from the Pub. Improv. Com. urging that bids be asked for sinking one or more artesian wells near the Turtle Creek pump house.

Arlington, S. D.—O. Claussen, of St. Paul, estimates the cost of a system of water works at $13,550.

Yazoo City, Miss.—The City Council has authorized the issue of $200,000 water, light and sewer bonds.

Springfield, O.—The City Council has decided to readvertise the $30,000 water works bonds.

Oroville, Cal.—The Palermo Land & Water Co. has asked for a 40-year franchise to lay pipes and supply water to this town.

Los Angeles, Cal.—The Miradero Water Co. has been incorporated, with a capital stock of $75,000. Directors: L. C. Brand, W. H. Taylor, of Los Angeles; Fred. H. Taft, Santa Monica, and others. Principal place of business, Los Angeles.

Phenix, R. I.—Engr. in Charge J. A. Latham, of Providence, writes that the Phenix Valley Water Co. has awarded the contract for constructing a reservoir to J. Vaughn, of Stamford, N. Y., for $40,000.

Chase City, Va.—The citizens have asked the Town Council to take steps toward the construction of a system of water works and the macadamizing of the principal streets.

Lorain, O.—City Engr. Chas. S. Fergnson writes that bonds to the amount of $32,000 have been authorized for water works extensions.

Freeport, O.—Corp. Clk. Walter Jones writes that bids will be received Aug. 16 for the construction of water works estimated to cost $5,000. Engr. in Charge, S. C. Kelly, Freeport.

Manning, Ia.—Bids are wanted Aug. 21 for the construction of a water tower, as advertised in The Engineering Record.

Albany, Ore.—The Albany Canal & Water Co., E. W. Langdon, Pres., has been formed to take over and improve the plant of the old water company.

New Philadelphia, Pa.—The New Philadelphia Water Co. has been incorporated, with a capital of $1,000. Stockholders: Alex. H. Scott, New Philadelphia; W. M. Faussett, Pottsville, and others.

Boston, Mass.—The only bid received July 26 at the Bureau of Yards & Docks, Navy Dept., Washington, for constructing a concrete and steel conduit and laying a 16-in. C. I. water main at the Navy Yard, Boston, was from the Aberthaw Const. Co., of Boston, at $55,564.

North East, Pa.—Boro. Secy. F. B. Comstock writes that at the election held July 29 it was voted to borrow $20,000 for extending and enlarging the water works.

Roundlake, Minn.—Bids will be received Aug. 6 for constructing a water works system, consisting of a wooden tank, on steel tower, gasoline pumping plant, pump house and a system of distributing mains with appurtenances. J. C. Thomsen, Village Recorder.

Allegheny, Pa.—Bids are wanted Aug. 12 for erecting an addition to the Howard St. pumping station. D. L. Fulton, Dir. of Dept. Pub. Wks.

Rockford, Ia.—A vote has been taken in favor of the construction of a standpipe.

Westbrook, Minn.—Plans prepared by M. B. Haynes, of Mankato, Minn., for a system of water works are reported to have been adopted.

Mt. Horeb, Wis.—This village is reported to have voted $12,000 for a system of water works.

Castana, Ia.—Town Clk. W. C. Newton writes that on July 28 an additional $3,000 bonds were voted for water works.

St. Ansgar, Ia.—Town Clk. C. T. Tollefson writes that the contract for constructing water works has been awarded to the Des Moines Bridge & Iron Wks., Des Moines, Ia., for $7,879.

West Milton, O.—John D. Force is said to have been engaged to prepare plans and estimates for a system of water works.

Lawton, Okla. Ter.—Bids are wanted by the City Council until Aug. 15 for constructing a system of water works. L. P. Ross, Chmn. Council Com.

Enfield, N. H.—Bids are wanted by the Water Comrs. until Aug. 12 for clearing and grubbing and removing all soil and vegetable matter from about 25 acres of land to be used as a reservoir, and also for constructing a puddle earth dam, 750 ft. in length, with a masonry core; also for a masonry waste weir and screen chamber with the necessary appurtenances. Everett B. Huse, Chmn.; Arthur W. Dudley, Engr., Manchester.

Sterling, Colo.—Local press reports state that Ch. Hydrographer F. H. Newell has recommended to the Interior Dept., Washington, that land on the north side of South Platte River be set aside for the first great national reservoir to be built under the new irrigation law.

Schuylerville, N. Y.—The proposition to establish a system of water works at a cost of $55,000 was adopted at the election held July 25.

Ft. Plain, N. Y.—Water works bonds to the amount of $20,000 have been sold.

Ft. Barrancas, Fla.—See "Government Work."

Rayne, La.—Bids are wanted Aug. 30 for $20,000 water and light improvement bonds. O. Broussard, Mayor.

Buffalo, N. Y.—New bids have been ordered readvertised for furnishing hydrants for the year ending June 30, 1903.

Fairview, W. Va.—Bonds to the amount of $10,000 have been voted for water works.

Los Angeles, Cal.—The Bd. of Water Comrs. has unanimously indorsed a plan for the improvement of domestic water works, which involves an expenditure of $235,000.

Lima, O.—The Council is considering the construction of a reservoir estimated to cost $97,840 to $146,793, according to the location.

Lincoln, Neb.—The City Council is reported to have voted to lay $12,000 worth of water main extensions.

San Francisco, Cal.—The Fire Com. of the Bd. of Superv. has requested the City Engr. to prepare plans for a salt-water system to be installed for the use of the Fire Dept., and for flushing sewers and other purposes.

Great Neck, L. I., N. Y.—Local press reports state that the Town Bd. of North Hempstead will soon let the contract for furnishing a water supply. Probably 40 hydrants will be required. Monroe S. Wood, Town Clk.

Hammonton, N. J.—The contract for furnishing and laying water pipe, with 5 10-in., 1 8-in., 12 6-in. and 12 4-in. gate valves, and 48 fire hydrants, has been awarded to Wm. John Smith, of Spring Lake, N. J., at a total of $17,888. His detail bid on C. I. pipe was as follows: 2,800 ft. 10-in., at $1.21; 300 ft. 8-in., at 92 cts.; 9,800 ft. 6-in., at 66 cts., and 8,600 ft. 4-in., at 47 cts.
The contract for constructing a steel standpipe, 12 ft. inside diameter and 115 ft. above top of foundations, has been awarded to E. Keeler & Co., of Williamsport, Pa., at his bid of $5,714, including foundations.

Boston, Mass.—The following bids were opened July 25 by the Metropolitan Water & Sewerage Bd. for laying cast-iron water pipe in Weston and Newton, including the construction of a coffer dam and the laying of 3 lines of pipes, each 350 ft. in length, under Charles River: Ward & Cummings, Boston, $33,564 (awarded); Metropolitan Cont. Co., Boston, $34,155; E. W. Everson & Co., Roxbury, $37,625; Dennis F. O'Connell, Dorchester, $45,023; Bruno, Salomone & Petitti, E. Boston, $47,626; Moore & Co., Boston, $52,801. The detail bid of Ward & Cummings was as follows: Building and maintaining coffer dam and pumping and draining, $14,887. Laying C. I. pipe—60-in. west of Sta. 16x55, 1,509 lin. ft., $3.25; 60-in. C. I. pipe east of Sta. 16x55, crossing Charles River, 1,060 ft., $4.85; 48-in., 80 lin. ft., $3; 36-in., 20 lin. ft., $2.90; 16 and 20-in. for blow-offs, 190 lin. ft., $1.50; rock excav., 200 cu. yds., $4; earth excav. for grading, 1,300 cu. yds., 80 cts.; setting 2 air valves, $10; chamber for 36-in. valve, $98; 8 chambers for blow-offs, air valves and manholes, $65; concrete masonry, 800 cu. yds., $7.

Tupelo, Miss.—Weatherford & Hildebrand, of Memphis, have been engaged to make a survey and estimates for a system of water works.

SEWERAGE AND SEWAGE DISPOSAL.

Avon, N. Y.—Village Clk. B. F. Salley writes that on June 28 it was voted to rebuild the W. Main St. sewer.

Monticello, Ind.—City Clk. W. J. Gridley writes new bids for constructing sewers 8, 9 and 10 will be received Aug. 22 by the Bd. of City Trustees.

Mansfield, O.—See "Paving."

Torrington, Conn.—Bids are wanted Aug. 12 for furnishing material and constructing sewers and appurtenances in numerous streets. Engineer's estimate, 9,220 lin. ft. 6 to 12-in. vitrified pipe; 252 lin. ft. 8 to 12-in. cast-iron pipe and 47 manholes. F. F. Fuessenich, Chmn. Bd. of Sewer Comrs.

Sioux City, Ia.—Local press reports state that about $16,000 will be expended by this city for storm sewers.

Washington, D. C.—The Dist. Comrs. have allotted $50,000 for the construction of sewers.

Yazoo City, Miss.—See "Water."

Hoboken, N. J.—City Clk. John Haggerty writes the proposed sewer system to drain Hoboken meadows will probably cost about $300,000. The Advisory Com. reported in favor of pumping system. Thos. H. McCann, Engr., Hoboken.

Elizabeth, N. J.—The City Council is considering a report by City Surv. Luster on the flooded districts of the city, in which he recommends the construction of certain sewers.

Orange, Tex.—The City Council has granted Col. W. D. Bettis and associates a franchise for constructing a sewer system.

St. Cloud, Minn.—City Engr. Chute has been directed to prepare plans and specifications and estimate the cost in extending the St. Germain St. sewer, which is to be of pipe 22-in. in diameter.

Lorain, O.—It is proposed to build 3 short outfall sewers at an estimated cost of $12,000; but bids will not be asked before Sept. Chas. S. Fergurson, City Engr.

Davenport, Ia.—Bids are wanted Aug. 5 for the construction of certain 10 and 15-in. pipe sewers. Thos. Murray, City Engr.

St. Paul, Minn.—Bids are wanted Aug. 7 for constructing a ditch in Aitkin County. Geo. A Ralph, Engr. for State Drainage Comn., Crookston. P. E. Hanson, Secy. Comn., St. Paul.

Johnstown, Pa.—City Clk. Geo. E. Hamilton writes that the city proposes to introduce a new sewer system in the near future, but the matter is still pending in the Councils.

Oakland, Cal.—The City Council has adopted plans and specifications prepared by the City Engr. for the 4th Ave. outfall sewer.

Indianapolis, Ind.—The Crown Hill Cemetery Asso. has agreed to pay $24,000 toward the cost of constructing Northwestern Ave. sewer. Total cost, $73,-000.

Altoona, Pa.—Local press reports state that City Engr. Harvey Linton will construct an experimental septic tank and rapid filter along the creek which carries away the sewage of the eastern end of the city, with a view to constructing, if experiment is successful, tanks and filters at a cost of $50,000.

Decatur, Ind.—The City Council has passed a resolution for the construction of the Gregory sewer, which is to be 10 and 15-in. tile.

Grafton, N. D.—City Aud. B. A. Provoost writes that the contract for constructing a sewer system, including 15,493 ft. 18 to 8-in. pipe sewer, 35 manholes and 87 catch basins, average cut 8 ft., has been awarded to Jas. Kennedy, of Fargo, N. D., at his bid of $14,501, submitted on July 26.

Grand Rapids, Mich.—The Common Council has passed a resolution for the construction of a sewerage system in the 12th Ward. L. F. Lamoreaux, City Clk.

Glenville, O.—Plans adopted by the Village Council provide for a storm sewer, 6-ft. near the outlet, for Garfield, Ludwig and Robinson Sts.

Erie, Pa.—The Council has passed an ordinance providing for the issue of $28,000 bonds for the main brick sewer in East Ave.

Dedham, Mass.—At a special town meeting held July 23 it was voted to appropriate $53,000 for the completion of the system of sewers now being constructed.

Omaha, Neb.—Bids will be received by the Bd. Pub. Wks. until Aug. 8 for constructing pipe sewers in Sewer Dist. No. 277. Andrew Rosewater, Chmn.

Geneva, O.—It is stated that bids are wanted Aug. 29 for constructing sewage disposal works and a pumping plant. B. F. Hunt, Village Engr.

Lawton, Okla. Ter.—Bids are wanted by the City Council until Aug. 15 for constructing a system of sewerage. L. P. Ross, Chmn. Council Com.

St. Louis, Mo.—Bids are wanted Aug. 15 for constructing brick and pipe sewers in several sewer Dists. Hiram Phillips, Pres. Bd. Pub. Improv.

Watertown, Mass.—Bids will be received by Chas. W. Stone, Town Treas., until Aug. 11 for $10,000 drainage bonds.

Morris Plains, N. J.—Prof. McMillen, of Princeton, is stated to have recommended a plan for the purification of the sewage of the Insane Hospital in this place, at an estimated cost of $40,000.

Jersey City, N. J.—Ch. Engr. Van Keuren has estimated the cost of proposed sewers as follows: Bay St., $14,210; Division St. relief sewer, $19,660; and reconstruction of Van Vorst St. sewer, at $8,000.

Grand Haven, Mich.—The City Council has ordered the Bd. of Pub. Wks. to secure estimates of the cost of platting the city for a system of sewers.

Gainesville, Ga.—This city has sold $50,000 bonds to be used as follows: $20,000 for beginning sewerage system, $20,000 for school and $10,000 for street improvements.

Cincinnati, O.—City Engr. Stanley has been directed to co-operate with the Millcreek Sewering Com. of the 25th Ward Improv. Asso. in adopting means of diverting sewage, which is now allowed to empty into the creek into other channels.

Boise, Idaho.—The City Council has passed an ordinance ordering sewers in Dists. Nos. 15, 17, 18 and 19.

Philadelphia, Pa.—Local press reports state that among the sewer contracts recently awarded was the contract for extending Cohocksink sewer, which was given to Geo. A. Vare, at $36 per ft.; total about $100,000.

Taylor, Pa.—An ordinance passed by the Council provides for the issue of $14,000 bonds for the construction of sewers. Wm. P. Giffiths, Burgess.

Brooklyn, N. Y.—The Bd. of Estimate has approved a resolution recommended by the Bay Ridge Local Bd., authorizing the initiation of proceedings to construct main sewers in 92d St. and vicinity at an estimated cost of $655,000.

Lestershire, N. Y.—The Village Bd. has engaged Knight & Hopkins, of Rome, to prepare plans and specifications for sewers.

Quakertown, Pa.—The Quakertown Sewerage Co. has been organized with John V. Ommeren as Pres. and W. H. Davis as Secy.

Bronxville, N. Y.—Engr. in Charge Chas. W. Leavitt, Jr., of New York City, writes that the following bids were opened July 21 for the construction of a sewerage system and septic tank, including 4,120 ft. of 18 to 8-in. pipe sewers, and 17 manholes. The trench to average 8 to 9 ft. in depth and be excavated mostly in sand with some rock; Robt. W. Smith, Newark, $16,950; Bellew & Merritt, Tuckahoe, N. Y., $14,998; Piro & Mottola, Mt. Vernon, $13,997; J. Maybury & Son, Passaic, N. J., $12,404; Besch & Flynn, 83 Third St., Troy, N. Y., $11,900 (awarded).

Montreal, Que.—City Engr. John R. Barlow writes that contracts for sewer construction, bids opened July 11, have been awarded as follows: To Jos. Menard, Montreal, Cuvillier St. for a distance of 200 ft., 2x3-ft. brick sewer, including excavation and refilling, $5.95 per lin. yd.; rock excavation, $2 per cu. yd. To J. Toussaint and C. Sauriot, of Montreal, Bertrand St., 2x3-ft. brick sewer, including excavation and refilling, $6.25 per lin. yd.; rock excavation, $1.50 per cu. yd.; Hotel de Ville Ave., 2x3-ft. brick sewer, including excavation and refilling, $6.24 per lin. yd.; rock excavation, $3.15 per cu. yd.; St. James St., 2x3-ft. brick sewer, including excavation and refilling, $14.70 per lin. yd.; rock excavation, $2.57 per cu. yd.

Des Moines, Ia.—City Engr. John W. Budd writes that the lowest bid received July 24 for Highland Park lateral sewers (27,300 lin. ft. 12-in. pipe, average cut 11 ft. in clay and gravel, 84 manholes), was from C. C. Loomis at 92 cts. per lin. ft.

The contract for sewers in 17th, 18th and other streets (bids opened July 21), in all 8,715 ft. of 18 to 24-in. pipe sewers, with 25 manholes, has been awarded to Kehoe & Son, of Des Moines, at $1.23 per lin. ft. Average cut, 11 ft. in clay and sand.

Bids opened July 22 for Highland Park intercepting sewer ranged from: Wm. Horrabin, of Iowa City, at $2.59 per lin. ft.; to O. P. Herrick, of Des Moines, at $2.97 per lin. ft. The contract calls for 5,136 ft. of 15 to 18-in. pipe and 48 to 36-in. brick sewer, with 33 manholes. Average cut, 11.5 ft. in clay and gravel.

Washington, Pa.—Boro. Engr. J. M. McAdam writes that the following bids were opened July 7 for sewer construction; the trench to be, according to profile, from 5 ft. fill to 22 ft. cut, and to be excavated in limestone soil, little rock: A, Wm. Pickett & Co., Washington, Pa., $24,593; B, Dickson & Applegate, Sewickly, Pa., $32,107; C, J. B. Sheats & Co., E. Pittsburg, Pa., $26,102; D, J. H. M. McQuaide, 5th Ave., Pittsburg, Pa., $23,929; E, Jno. Dell & Co., Braddock, Pa., $29,064; F, Rosser & Maloney, Bellaire, O., $21,-326; G, R. T. Hallam & Sons, Washington, Pa., $26,-989; H, Sweeny & Huston, 32d St., Pittsburg, Pa., $23,311; I, W. H. Herr, Altoona, Pa., $18,721 (awarded). For detail bids see accompanying table:

Bidders.	11,638 ft. 20-in. tile.	369 ft. cast iron pipe.	100 ft. 6-in. sewer.	200 yds. concrete.	60-in. wr't iron pipe.	13 manholes.
A	$1.78	$3.90	$.09	$6.50	$9.50	$43.00

Centerville, Ind.—Res. Engr. J. T. Frame writes that the contract for constructing cement or brick sidewalks, bids opened July 24, has been awarded to Wm. Rehling, of Richmond, Ind., as follows: 14 cts. per sq. ft. finished for brick or cement walk; prices per lin. ft. for 4, 5, 6 and 10-ft. brick or cement walks were respectively 56 cts., 70 cts., 84 cts. and $1.40. Total, $5,000.

Morristown, N. J.—Bids will be received by the Bd. of Chosen Freeholders at Morristown until Aug. 12 for furnishing crushed trap rock for use on the Co. State Aid Roads. In all about 10,000 tons will be needed annually. S. A. Becker, Dir. of Bd.

Mansfield, O.—Bids are wanted Aug. 23 for paving with brick or asphalt on Mulberry St.; also on portions of Bowman St. with brick or block; also for constructing 8-in. sanitary sewers in Washington Ave. and West Arch St. D. S. Koontz, City Clk.

Detroit, Mich.—The Common Council has passed resolutions providing for the paving of 4 streets with cedar block, at a total estimated cost of $64,822.

Napoleon, O.—Village Engr. C. N. Schwab writes that the contract for paving Perry St. and Oakwood Ave., bids opened July 22, has been awarded to Cartwright & Hennessey, of Troy, O., for $27,069; the contract calls for 18,000 sq. yds. of Logan or Met. block pavement with cement filler.

Menasha, Wis.—According to press reports the Council will expend $20,000 in street improvements.

Auburn, N. Y.—City Clk. E. H. Herrling writes that the following bids were received for asphalt paving on one street, estimated to cost $30,000: Barber Asphalt Paving Co., $1.99 per sq. yd.; Warner-Quinlan Asphalt Paving Co., Syracuse, $1.84½ per sq. yd.

Belle Vernon, Pa.—Bonds to the amount of $10,000 have been voted for street paving and fire apparatus.

Charlottesville, Va.—The Street Improv. Com. has reported, giving the estimated cost of paving Main St. with brick as $50,000 and the cost of macadamizing certain cross and parallel streets at $26,600. The Com. recommends that bonds to the amount of $80,000 be issued for said improvements.

Leavenworth, Kan.—The Council has ordered a portion of 4th St. paved with brick. Estimated cost, grading and curbing, $1,984; artificial stone curbing, $4,498; paving, $28,033.

Lowell, Mass.—The Bd. of Aldermen has adopted the order to borrow $38,950 for paving.

Watertown, N. Y.—The Bd. of Pub. Service is reported to have awarded to Warren Bros. Co., of New York, the contract for a bituminous macadam pavement in State St. for $40,661.

Spokane, Wash.—The City Council has ordered Main Ave. to be paved; probably asphalt will be used.

San Francisco, Cal.—The Bd. of Supervisors has ordered Beale St. repaved with basalt block at a cost of $10,000, and Mission St. paved with bituminous rock at a cost of $10,000.

New Orleans, La.—The Dock Bd. is having plans and specifications prepared for an additional amount of Georgia granite paving along the wharfs; about 25,000 sq. yds.

Three Rivers, Mich.—At the special election held July 28 it was voted to issue $39,000 bonds for paving Flint Ave. and St. Joe St.

Trenton, N. J.—Mayor Katzenbach has signed ordinances for the repaving of State St., and authorizing a bond issue of $35,000 for repaving with asphaltum over Belgian block on Hanover, Bank and other streets.

Chester, W. Va.—Recorder J. S. D. Mercer writes that at the election held July 28 it was voted to issue $20,000 bonds for street improvements.

Portsmouth, Va.—The City Council has appropriated $50,000 additional for street improvements, making a total of $100,000 to be expended this year. Bascom Sykes, City Engr.

St. Clair, Mich.—Willis F. Brown, Consulting Engr., Toledo, O., is preparing plans and specifications for 30,000 yds. of brick paving, for which bids are about to be received.

Chase City, Va.—See "Water."

Lorain, O.—Bids are wanted Aug. 25 for 13,000 ft. of 5x24-in. stone curbing and 24,000 sq. yds. of brick paving on 6-in. concrete foundation. Chas. S. Ferguson, City Engr.

Harrisburg, Pa.—City Clk. Chas. A. Miller writes that the City Solicitor is now preparing an ordinance to pave with sheet asphalt about 360,000 sq. yds.

Brooklyn, N. Y.—Bids are wanted Aug. 6 for 62,860 sq. ft. of bluestone flagging for sidewalks in numerous streets. J. Edw. Swanstrom, Pres. Boro. of Brooklyn, New York City.

Long Island City, N. Y.—Bids are wanted Aug. 7 for 3,350 sq. yds. of granite block pavement, with 9,600 sq. ft. of new flagging on a portion of 9th Ave. Jos. Cassidy, Pres. Boro. of Queens, New York City.

Frederick, Md.—Bids are wanted Aug. 9 for paving approximately 3,800 sq. yds. with vit. brick or block on East Church St.; also 1,600 ft. of stone curbing. Geo. Edw. Smith, Mayor.

Milwaukee, Wis.—Local press reports state that all bids opened July 22, for paving 16th St. viaduct with creosoted pine block, in all 17,000 sq. yds., have been rejected and that new bids will be asked. The lowest bid received was from Paul Froemming, of Milwaukee, at $2.67 per sq. yd.

Asphalt paving contracts have been awarded to the Barber Asphalt Paving Co. as follows: 4 streets, in all 13,092 sq. yds., at $2.30 per sq. yd., and 1 street, 4,214 sq. yds., at $2.40 per sq. yd.

York City, Pa.—The Common Council has passed an an ordinance directing the Highway Com. to cause a portion of Susquehanna Ave. to be macadamized, with brick and stone gutter.

Tuscola, Ill.—The City Council has passed ordinances providing for 23 blocks of brick pavement, for which contracts are to be let at once, according to local press reports.

Pentwater, Mich.—The Council has directed the City Engr. to prepare estimates of the cost, and plans for paving Oakland Ave. and Jackson St.

Crawfordsville, Ind.—The City Comrs. have completed their final report on the paving of Main and Green Sts. Total estimated cost, $55,122.

Bloomsburg, Pa.—The Council has instructed the Town Engr. to prepare specifications for the paving of a portion of Main St.; probably brick will be used on a concrete foundation.

Syracuse, N. Y.—The City Engr. has recommended the paving with brick of several streets at a total estimated cost of about $65,000.

Marinette, Wis.—The County Bd. has under consideration the building of 17 miles of road.

Wilmette, Ill.—Bids will be received by the Bd. of Local Improv. until Aug. 7 for curbing, paving with brick, and otherwise improving portions of West Ave. V. B. Roberts, Engr., Reaper Blk., Chicago. Henry B. Gates, Chmn.

Mechanicville, N. Y.—Bids will be received by the Village Bd. of Trus. until Aug. 6 for constructing vitrified block pavement on a concrete foundation for Main and Railroad Sts. C. E. Hicks, Village Engr.

Niagara Falls, N. Y.—Geo. F. Diermer, City Clk., writes that bids will be received about Sept. 1 for paving on 4th, 5th, 11th and 13th Sts. Probable cost, $25,000.

St. Louis, Mo.—Bids are wanted Aug. 8 for paving with vitrified brick on portions of numerous streets. A 6-year guarantee to accompany each bid. Hiram Phillips, Pres. Bd. Pub. Improv.

Baltimore, Md.—Bids are wanted Aug. 6 for grading, curbing and recurbing and paving with vitrified brick on a portion of Park Ave. B. T. Fendall, City Engr.

Albany, N. Y.—The Bd. of Supervisors on July 22 passed resolutions providing for the improvement of numerous Albany Co. highways.

Brooklyn, N. Y.—Bids are wanted Aug. 7 for repaving with asphalt on old asphalt foundation the northerly portion of Coney Island Concourse; also for furnishing and laying hexagonal asphalt tiles on Coney Island Concourse. Wm. R. Willcox, Comrs. of Parks, New York City.

New Brighton, S. I., N. Y.—Bids are wanted Aug. 8 for grading and paving with asphalt (6,700 sq. yds., including binder course,) and granite block (1,500 sq. yds. with cement joints), with cement foundation, a portion of Richmond Road; for asphalt pavement, 5,400 sq. yds., with concrete foundation, on a portion of Richmond Terrace; for asphalt block pavement, 2,200 sq. yds. with concrete foundation, on a portion of Water St.; for granite block pavement, 2,650 sq. yds., with concrete foundation or another portion of Richmond Terrace; and for granite block pavement 4,600 yds., with concrete foundation on a portion of Jersey St. Geo. Cromwell, Pres. Richmond Boro., New York City.

Milwaukee, Wis.—Bids are wanted Aug. 5 for furnishing material, grading and paving with asphalt on a concrete foundation, a portion of 2d Ave. Chas. J. Poetsch, Chmn. Comrs. Pub. Wks.

Warren, O.—Bids are wanted Aug. 25 for furnishing material and paving with asphalt block, brick or macadam on portions of several streets. A. L. Jameson, City Clk.

Weehawken, N. J.—Bids will be received by the Township Com. Aug. 5 for regulating and paving with asphalt a portion of Angelique St. Thos. Carroll, Township Clk.

Rome, N. Y.—Bids will be received by the Common Council until Aug. 8 for paving with asphalt, Warren's bituminous macadam waterproof, and brick on a portion of W. Embargo St. Jay Capron, City Engr.

Omaha, Neb.—Bids will be received by the Bd. Pub. Wks. until Aug. 8 for curbing and paving with either asphaltum, vitrified brick, stone block or vitrified block in Street Improv. Dist. No. 803. Andrew Rosewater, Chmn.

Brooklyn, N. Y.—Bids will be received by the Boro. Pres., J. Edw. Swanstrom, until Aug. 13 for furnishing material and paving with asphalt on portions of numerous streets, in all about 67,100 sq. yds.

Medford, Wis.—It is stated that bids are wanted Aug. 15 for 3,300 ft. of cement curb and gutter, and 14,000 sq. yds. of macadam pavement. W. G. Kirchoffer, Engr., Baraboo, Wis.

Fall River, Mass.—Local press reports state that the Supt. of Streets will receive bids for 150,000 granite paving blocks.

New York, N. Y.—Bids are wanted Aug. 12 for regulating and repaving with asphalt on portions of numerous streets. Jacob A. Cantor, Boro. Pres.

Long Island City, N. Y.—Bids are wanted Aug. 14 for regulating and repaving with asphalt on portions of several streets. Joseph Cassidy, Boro. Pres.

Michigan City, Ind.—H. M. Miles, City Engr., writes that bids will be received until Aug. 18 for paving with asphalt and constructing combined curb and gutter on W. 7th St. Estimated cost, $10,000.

City Engr. H. M. Miles writes that the following bids were opened July 21: *a*, asphalt paving, per sq. yd.; *b*, curbing and gutter; *c*, grading, per cu. yd.; *d*, total: Western Construction Co., Indianapolis, Ind., *a* $1.89, *b* 60 cts., *c* 29 cts., *d* $13,080; Barber Asphalt Paving Co., Indianapolis, Ind., *a* $1.95, *b* 65 cts., *c* 30 cts., *d* $13,632.

Long Island City, N. Y.—The following bids were opened July 24 by Jos. Cassidy, Boro. Pres., for repaving with asphalt on relaid block pavement and repaving with granite block on sand: A, Continental Asph. Pavg. Co.; B, Interstate Pavg. Co.; C, Asph. Const. Co.; D, Barber Asph. Pavg. Co.; E, Uvalde Asph. Pavg. Co.; F, M. T. Meagher; G, Green River Asph. Pavg. Co.:

Borden and Jackson Avenues.

Martinez, Cal.—The Supervisors of Alameda and Contra Costa Counties have adopted plans for the tunnel to be built connecting the two counties by means of a wagon road on an easy grade. The tunnel will be about 1,100 ft. long, and the estimated cost is $33,259 to Alameda Co. and $46,456 to Contra Costa Co.

Portland, Ore.—Consulting Engr. Jas. E. Blackwell, Dexter Horton Bldg., Seattle, Wash., writes that the following bids were opened July 25 by the Port of Portland Comrs. for the construction of a wooden drydock: *a*, amount as per specification; *b*, amount if top and bottom chords are in 2 pieces only; *c*, time to complete: Robt. Wakefield, Portland, *a* $160,000, *b* $165,000, *c* 12 mos.; J. E. Bennett, Portland, *a* $162,500, *b* $167,750, *c* 12 mos.; J. B. Bridges, Portland, *a* $166,750, *b* $171,250, *c* 12 mos.; N. J. Blagen, Portland, *a* $170,000, *b* $176,000, *c* 12 mos.; Bringham & Hoska, Seattle, *a* $174,500, *b* $178,500, *c* 12 mos.; Jos. Pacquet, Portland, *a* $174,900, *b* $178,000, *c* 13 mos.; Portland Ship Bldg. Co., Portland, *a* $220,000, *c* 12 mos.

New York, N. Y.—The following bids were opened July 24 by the Dept. of Parks for improving the northern portion of the Botanical Garden in Bronx Park:

Items and Quantities.	Wm. J. Moore.	Bartholomew Dunn.
Earth excavation	$1.00	$.30
Rock excavation	.....	1.50
Filling 56,000 yds.	.40	.66
Pavement	1.00	1.00
Pipe, 10-in.	1.00	.45
Pipe, 1,000 ft. 8-in.	1.00	.35
Pipe, 2,958 ft. 6-in.	1.00	.25
Land tile, 500 ft. 5-in.	.10	.16
Tile, 700 ft. 4-in.	.10	.13
Tile, 3,100 ft. 3-in.	.10	.10
Tile, 12,600 ft. 2-in.	.10	.08
Water pipe, 500 ft. 4-in.	1.00	.80
Iron pipe, 7,200 ft. 2-in.	.13	.12
Walk basins, 40	50.00	40.00
Street washers, 200	5.00	7.00
Brick culvert, 200 ft.	8.00	6.75

New bids for this work will be opened Aug. 7. Wm. R. Willcox, Comr. of Parks.

NEW INDUSTRIAL PLANTS.

The Clearfield, Pa., Steel & Iron Co. has contracted for the erection of buildings measuring 360x220 ft. The power plant required will be about 1,500 H.-P.

The Bostwick Steel Lath Co., Niles, O., is erecting a new plant, the main building to be 60x250 ft. The capacity of the power plant has not been decided.

Contracts will soon be let for the new plant of the Cleveland, O., Pneumatic Tool Co.

W. L. Hill, Sharon, S. C., expects to establish a brick plant to have a daily capacity of 30,000 to 40,000. It is also his intention to make tile.

The Arcadia Mills, Spartanburg, S. C., will erect a mill to contain 10,000 to 12,000 spindles, and about 300 looms. C. R. Makepeace & Co., Providence, R. I., archts.

The Atlanta, Ga., Car Wheel & Mfg. Co. will erect a plant to have a daily capacity of about 200 wheels. The main building will be 230x119 ft.

The Brylgon Foundry, Reading, Pa., has outgrown its present plant and contemplates the erection of a larger.

The Menasha Paper Co., Ladysmith, Wis., will erect a 1-machine mill, including a 40x208-ft. machine room, 40x56-ft. beater room, 30x47-ft. boiler house and a 40x64-ft. finishing room. The capacity of the power plant will be 525 H.-P.

The Standard Roller-Bearing Co., 2326 Market St., Philadelphia, is erecting a 200x100 ft. factory and an 80x50-ft. case-hardening and tempering plant. A 200-H.-P. engine will be installed.

The Colonial Foundry & Machinery Co., So. Norwalk, Conn., will erect a 40x125-ft. machine shop, 90x108-ft. foundry and a warehouse 40 ft. square. A power plant of about 30 H.-P. will be installed.

The Malleable Iron Fittings Co., Branford, Conn., is ready to begin work on a 200x118-ft. addition to its annealing department, and has plans for a 2-story, 150x80-ft. core shop, both buildings to be of fireproof construction, with steel beams and cement floors and roofs. The company also contemplates the erection of another foundry and steel furnace.

The Atmospheric Products Co., Gluck Bldg., Niagara Falls, N. Y., is erecting a 2-story, 125x50-ft. machine shop and experimental laboratory.

The People's Ice & Cold Storage Co., Columbus, Miss., is in the market for a 15-ton ice machine.

The Burnside, Ky., Electric Light & Power Co. expects to install a 15-ton ice plant.

Walker Bros., Viola, Ore., will erect a 24x150-ft. saw mill to have a 100-H.-P. power plant.

Wm. Edwards, Plymouth, Fla., is considering the installation of a small ice plant.

The Emerson Electric Mfg. Co., 714-718 St. Charles St., St. Louis, Mo., has let a contract for a 6-story and basement, 108x150-ft. building, to be equipped with two passenger and two freight elevators, two 50-Kw. generators, engines, boilers and sprinkler system.

The mill of Billings, Beals & Co., Avoca, N. Y., recently burned, will probably be rebuilt to its former size. The mill's capacity was 50 bbls. wheat, 50 bbls. buckwheat and 25 tons feed, and it was run by a gas engine.

The Griswold Mfg. Co., Erie, Pa., intends to erect a power plant of 300 to 400 H.-P. capacity, using electrical distribution, and a foundry.

The American Spinning Co., Greenville, S. C., will erect a 104x141-ft. addition to contain 25,000 spindles.

The Classic Corset Co., 189 Fifth Ave., Chicago, is in the market for a gas engine to generate 60 H.-P. electricity, dynamo and motors.

BUSINESS NOTES.

The Cleveland, O., Pneumatic Tool Co. has opened offices at 411 Park Bldg., Pittsburg, where it will be represented by Chas. L. Nelson, and at 34 Lemoine St., Montreal, Can., where it will be represented by N. J. Holden & Co.

The Springfield, Mass., Street Ry. has placed its third order for Green economizers.

The Allis-Chalmers Co., Chicago, has declared a fifth consecutive quarterly dividend of 1¾ per cent., payable Aug. 1 out of net earnings.

The Buffalo Forge Co. reports the following among its recent orders: Two 70-in. fans for heating and ventilating, direct-connected to Buffalo engines, and a 130-in. pulley fan for mechanical draft for Copenhagen; an induced draft plant and a 23-H.-P. engine for electric lighting in Dutch Guiana; five 45-H.-P. engines for driving generators and a 38-H.-P. engine for a pumping equipment for Manzanillo, Cuba; a 20-H.-P. vertical engine to Geestemunde, Germany; a 15-H.-P. double vertical single-acting engine to Gothenburg, Sweden; a 60 in. fan to Glasgow; a 140-in. fan with heaters to Barrow-in-Furness, Eng.; an 80-in. fan and heater and a 90-in. pulley fan and a 30-H.P. horizontal engine to London; a 120-in. fan and six 60-in. fans to Manchester, Eng.; an 80-in. fan for mechanical draft, to Victoria, B. C.; a 110-in. fan for mechanical draft to Halifax, N. S.; a 70 and a 100-in. fan to Portland, Ore.; a 40-in. fan to College Station, Tex.; a 100-in. fan direct-connected to a Buffalo engine to San Francisco; two 60-in. fans to New Orleans, La., and a 25-H.-P. horizontal engine to Gretna, La. The company has also received an order from the Continental Coal Co., Glouster, O., for three 250-in. fans for ventilating in its mines. They have three-quarter housing and are of the special width of 72 in. The sides are built of extra-heavy steel plate and are thoroughly braced with angle irons to prevent all vibration. The blast wheels of these fans are of the usual centrifugal type. The radial blades or vanes with backwardly curved tips are supported by two spiders of wrought-iron tees springing from cast-iron hubs and are further stiffened by the conical side plates. The fan shaft is supported independently of the housing by two standard Buffalo outboard bearings mounted on masonry pedestals. This plant is similar in many respects to that of the Modoc Coal Mining Co. at the same place, recently installed by this company.

Wm. B. Shaffer, Nazareth, Pa., is interested in the erection of a 10-kiln plant for the Superior Portland Cement Co. at Martin's Creek, Pa. All contracts have been let.

The Joseph Dixon Crucible Co. is installing in its plant at Jersey City, N. J., an engine built by the Ball Engine Co., Erie, Pa., direct connected to 100-Kw. generator.

The National Color Type Co., Chicago, is installing an electric plant for power and light. The engines will be furnished by the Ball Engine Co., Erie, Pa.

Westinghouse, Church, Kerr & Co. report the following among orders recently received: Two 6,000-H.-P. vertical 3-cylinder compound engines for the New York Edison Co.; Rapid Transit Subway Construction Co., New York, three 1,250-Kw. turbo-generator sets and two 400-H.-P. vertical marine type cross-compound engines; Stanley Rule & Level Co., New Britain, Conn., a 600-H.-P. vertical cross-compound direct-connected marine type engine; Baldwin Locomotive Works, Philadelphia, a 700-H.-P. vertical cross-compound marine type direct-connected engine; Syracuse Ry. Construction Co., Auburn, N. Y., two 1,000-H.-P. cross-compound horizontal Corliss engines; Springfield, Mass., St. Ry. Co., a 3,000-H.-P. vertical cross-compound Corliss engine; Illinois Steel Co., So. Chicago, Ill., a 1,750-H.-P. horizontal cross-compound engine; Hartford, Conn., St. Ry. Co., a 1,750-H.-P. horizontal cross-compound Corliss engine direct connected to Westinghouse railway generator and switchboard; DeBeers Consolidated Mines Ltd., So. Africa, 1,000-Kw. turbo-generator outfits; Cleveland, Elyria & Western Ry. Co., Elyria, O., 1,000-Kw. turbine outfits; West Penn Ry. & Lighting Co., three 1,000-Kw. turbo-generator outfits; Roslyn, L. I., Light & Power Co., two 400-Kw. turbo-generator units; Consolidated Rys., Light & Power Co., Wilmington, N. C., a 400-Kw. outfit; Johnston Harvester Co., Batavia, N. Y., a 400-Kw. unit; E. F. Goodrich Co., Akron, O., a 400 and a 750-Kw. unit; seven turbines aggregating 41,000 H.-P., the largest unit being 5,000 Kw., for furnishing power for an underground train service in London, Eng.; Land Title Bldg., Philadelphia, four 160-H.-P. compound single-acting engines; Great Northern Steamship Co., four 125-H.-P. direct-connected engines; Chicago, St. Paul, Minneapolis & O. Ry. Co., St. Paul, Minn., two 250-H.-P. direct-connected compound engines and a 30-H.-P. standard direct-connected engine; Boston & Albany R. R., Boston, a 350-H.-P. compound engine; City of Owensboro, Ky., a 350-H.-P. direct-connected compound engine, switchboard and Roney stokers; Trumbull St. Pumping Station, Washington, D. C., 200-H.-P. direct-connected compound single-acting engine.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Development in the Design and Construction of High Dams.

The advances made in the demands connected with irrigation enterprises and hydraulic power plants, no less than those which have grown out of the necessities of great public water supplies for large cities, have made it imperative to seek new and economical features of design for high dams. The long and even ancient use of masonry of good quality is sometimes considered to have placed masonry structures in a certain measure among those not capable of further development for the purposes of modern engineering, but nothing is much further from the facts of the case. Engineers are accustomed to phenomenally rapid evolution in various types of design and in the methods of production of iron and steel structures. While it is highly probable, if not certain, that correspondingly rapid advances cannot be expected in the design of structures which have heretofore been built in masonry, it is a fact that the latter material has partaken in a large measure of the progress which characterizes recent engineering practice. This observation is true both of masonry bridges and high dams, indeed it is true of every structure or portion of a structure in which masonry has come to be used. This is not more pronounced in any branch of engineering work than in the construction of high dams, which have been brought to that stage in which they are no longer always of masonry.

The large irrigation enterprises of the Western States and Pacific coast of this country have in their evolution produced some very interesting instances of construction, if indeed they may not be considered epoch-making in the design and construction of dams. Whenever stone and concrete have been employed in the construction of dams it has usually been one of the fundamental principles of design so to use them as to make the mass monolithic, and the principle is undoubtedly a sound one. In the structures where rock-fill constitutes a large part of the mass, however, there is obviously no application of this fundamental maxim. In many respects the rock-fill feature of a dam is apparently a blunt violation of some of the soundest principles of construction, and yet it has been found to have its legitimate field of use. It is certainly economical, indeed, that is its raison d'etre. The building of great dams for irrigation reservoirs in the West could only have been accomplished by a degree of economy in design heretofore unknown or never even dreamed of in this class of engineering works. One of the most marked instances of this class of dams is that of the plant of the Pike's Peak Power Company, near Victor, Colo. It was fully described in the columns of The Engineering Record of July 19, 1902. The height of this dam is 70 feet and the rock-fill portion is used to support on its up-stream side a continuous riveted plate steel face varying from one-half inch thick in its lowest portions to one-fourth inch in its highest. The joints of these steel plates are so constructed with steel angles as to give it ample capacity for expansion and contraction. The lower edge and ends of the steel face are solidly embedded in concrete filled rock trenches. Calked as in boiler work, the face forms an absolutely impervious curtain across the entire gorge or valley in which the dam is located. The supporting face of the rock-fill is laid as a smooth pavement but does not receive the steel plates direct, a six-inch layer or cushion of sand, gravel and sedimentary deposit being provided between. This entire structure is certainly a most marked and interesting development in the design of what may properly be called high dams. Most Continental and British engineers, even at present, would probably consider such designs at least rash, but experience already gained in connection with similar works shows that it is legitimate engineering construction, admirably adapted to meet the demands of the enterprise which it is to serve.

There are other high dams which show that even earth embankments may be safely and economically used where anything short of a costly masonry structure would have been generally thought ill-judged and unsound engineering but a few decades ago. Three such structures are the Druid Lake dam for the Baltimore water-works, the San Leandro dam of the water supply of Oakland, Cal., and the Tabeaud dam of the Standard Electric Company, of California, near Jackson in that State. The last has a crest about 123 feet above the natural surface and sustains water pressure from a maximum depth of about 92 feet. The other two, however, are but little less in height and sustain but little less depth of water. All three of these structures may be considered as demonstrating the applicability of properly founded and properly constructed earth embankments as dams of practically any height. A reference to the methods of construction of these dams will disclose a great respect for certain fundamental principles of design. In the first place, their foundations, like those of masonry structures, are carried down to bed rock or its equivalent, so that the seepage or passage of water through or underneath those foundations is rendered impossible. Wherever necessary or possible ample drainage of the foundations is always provided. Again, the character of material forming the mass of the embankment was chosen under the closest inspection and put in place with scrupulous care so as to produce as near as possible an absolutely impermeable mass. The Tabeaud dam possesses the characteristic of being designed without any core wall of either masonry or clay puddle, except for a small elevation above the foundation bed. The material of the embankment, however, was specified to contain about 70 per cent. of clay and 30 per cent. of gravel less than 2 inches in diameter and to be spread and compacted in final position so as to produce the best possible results.

It will be remembered in the discussion of the proposed great dam at Bohio on the Panama canal route by the French engineers of the New Panama Canal Company, that they considered an earth dam of somewhat less than 70 feet in height about the limit of safe construction. The present and preceding presidents of the Institution of Civil Engineers have also, in their presidential addresses, placed the seal of their disapproval on earth embankments designed as dams for greater heights than about 100 feet. These interesting and successful incidents of American dam construction show that the limits thus conservatively placed upon this class of engineering works are not necessarily final. Indeed, with reasonable care in founding an earth embankment upon such solid and impervious foundation bed as rock or its equivalent for such a purpose, and with other features so designed as to shut off absolutely the flow of water underneath and with a practically impervious bank, which it is perfectly practicable to attain, guarded with pavements on both the upstream and downstream sides if advisable, there seems to be no basis as yet on which a limiting height of earth dam may be placed. The design of these structures has been born of conditions under which they have been imperative as the expense of solid masonry work would have been prohibitive. They have served sound engineering purposes and they point the way to further economical development of high dam construction under circumstances where earth embankments, or even earth embankments combined with rock fill and other accompanying features of design, are justifiable by the canons of the best engineering practice.

Large Gas Engines.

A steady increase in the size of gas engines has taken place since the machine was put on the market in this country, about twenty-five years ago, and now units of over 100 effective horse-power are seen so frequently as to excite no special interest. It is a fact to be regretted, however, that some of the erroneous ideas concerning these machines, derived from ignorance during the introductory period of small engines, still cling to the modern engine and materially impede its progress. The worst of these fallacies is probably the one which credits the gas engine with ability to take care of itself. For all the evils following the application of such an idea to engine room practice, the builders are no doubt largely responsible, inasmuch as the circular of a few years ago generally assured the prospective purchaser that the engine described required no care beyond starting, occasionally oiling, and stopping. The almost invariable result was that the engine was left to fulfill the promises of the builder under the care of a man, who, if not totally unacquainted with machinery, knew very little about the action of the gas engine.

When the engine was small and the services of a good machinist available in cases of emergency, the engine generally gave good results by virtue of its real merit; but when the same engine room policy came to be applied to larger engines, trouble usually resulted, and dissatisfied users originated the common opinion that gas engines are all right in small size, but large ones are not reliable.

The extremely cheap natural gas in some parts of the country and costly steam fuel in others have led a fair number of good concerns to brave public opinion by installing large gas engines for important duty. In almost every case of this kind, in which careful judgment has been exercised in the selection of the engine, results have been good. These large engines represent a considerable outlay of capital, and as a rule competent men are placed in charge, the wages of such men being easily justified by the increased reliability and economy of the plant.

If a gas engine has work to do which is of any importance, it will always pay the owner to assure himself that the man who operates the engine is familiar with every detail of its construction, and operation. All adjustments should be made as soon as needed, not postponed until the engine stops nor until it fails to start from lack of adjustment of important parts. Certain parts of every gas engine are subject to wear and are not adjustable. Duplicates of such parts should be kept on hand so far as possible. There are, also, some of the more delicate parts, including springs, which are liable to break, and should always be kept on hand.

When a plant is of considerable size it would be well to have indicator diagrams taken at certain intervals, in order to observe the internal action of the engine. By this means a reliable record can be kept of ignitor and valve adjustments, and it is very little, if any, more difficult to obtain than one from a steam engine. If indicator diagrams are insisted upon when the engines are bought, the purchaser can always compare the running condition of his engine with its condition when on the manufacturer's test stand. It is perhaps needless to say that no reputable manufacturer would be likely to ship an engine from his shop without first testing it with both the brake and indicator, and the records of such tests should be open to examination by the purchaser.

The simplicity of the gas engine and the apparent ease with which it can be constructed have led many men to believe that they could improve it. A few have, perhaps, succeeded in some details, and if the remaining part of the engine is good, their efforts are generally successful. These cases are the exception rather than the rule, as a man may be a very good mechanic and machine designer, and yet fail hopelessly from lack of knowledge of the principles underlying the action of the gas engine. An engine which is correct theoretically and shows lack of mechanical skill, is just as bad. Familiarity with the modern practice, knowledge of the theory, and a high order of mechanical skill are absolutely necessary for the production of a well designed gas engine of large size, and the idea that any ordinary machinist can produce such a machine is dangerous. In order to produce a reliable, uniform product at a moderate price, special machinery must be used to a certain extent, and it is well to look into the shop methods of any builder before purchasing an engine from him. A fairly good idea can be formed as to the interchangeability of parts and this feature is very important.

An Undiscovered Leak in a 10-inch water pipe, which caused considerable damage, is described as follows in the 1901 report of Superintendent R. C. P. Coggeshall, of the New Bedford Water Board: The break was probably due to settlement, as the pipe was found broken square across. The leak had undoubtedly been running some time when discovered. It was bitter cold and the ground was frozen several inches deep. Its first appearance was at a considerable distance from the break; meanwhile the water had forced an entrance into the sewer, carrying with it a lot of earth filling, which was deposited more or less inside the sewer. When the frozen surface was broken through, an immense cavity was discovered. It was startling to know that such a hole could exist so near the surface without giving evidence of its existence.

Power Plant of the Central Lard Company, Jersey City, N. J.

The Central Lard Company has recently completed on Seventeenth and Coles Streets, Jersey City, N. J., a new factory which is particularly interesting as regards power production and transmission. The factory comprises a four-story brick building 200 feet long and 66 feet wide with an ell at one end 68 feet wide extending backward 65 feet, a 28x63-foot concrete-steel building enclosed by the ell and a 70x87-foot brick power house. A considerable amount of heating, cooling and pumping is required in the process of manufacture, and all of this, in addition to various other power demands, general lighting and water supply, is furnished by the power plant. The heating is by steam, the cooling by brine, the lighting and the pumping, except in a number of instances where considerable regulation is necessary, by electricity, and the water supply by means of the air lift. The power plant accordingly contains generating sets, refrigerating machinery and air compressors. Of the power equipment, special mention may be made of the steam and boiler-feed connections at the boilers and the unusual method of utilizing as far as possible the heat contained in the exhaust steam, the engines being run non-condensing.

The power house contains a boiler and an engine room, each the full length of the building, the former about 38 feet wide and the latter 27 feet. The engine room floor is at street grade level, and 8 feet above the boiler-room floor, which is of waterproofed concrete construction, the power house being located, as is the whole factory, on made ground. The foundations are mainly composed of piling and concrete, but under the engine room and a portion of the boiler room, brick arches of about 8 feet span were built on the piles and the concrete laid on these. There is no basement under the engine room, and steam lines are carried overhead into it and exhaust pipes laid in trenches formed in the concrete. The engine room contains the generating units, the air compressors and the refrigerating machinery. The feed pumps and feed-water heater are located in the boiler room. Coal is stored in a vault built against the outside boiler-room wall, the coal being shoveled from cars on a siding into the vault, which has a capacity for 10 days' operation of the plant. There are twelve openings from it into the boiler room with slide doors and three larger openings for the passage of wheelbarrows.

The boiler equipment consists of four Babcock & Wilcox water-tube boilers, set in two batteries with space for a third; the boilers are fitted with American automatic stokers and supplied with natural draft from a concrete-steel chimney, constructed according to the Ransome system, as described in detail in The Engineering Record of November 30, 1901. The stoker hoppers are filled by hand from the coal vault and are supplied with forced draft from a Sturtevant 5x2¾-foot centrifugal blower chosen large enough to provide for the ultimate boiler plant. The fan is operated at 460 revolutions per minute by a 40-horse-power Sprague motor. Each boiler contains 126 tubes 4 inches in diameter and 18 feet long, set 14 wide and 9 high, and two 36-inch drums 20 feet 4 inches long. Two steam mains are provided, one for 150 pounds pressure, supplying the engines, compressors, boiler feed pumps and heating coils in tanks requiring high temperature, and the other for 100 pounds pressure, for the refrigerating apparatus and for heating purposes in the factory. The method of making the steam connections is shown in the accompanying plan of the station and cross-section of boiler room. The steam connections into the 100-pound or auxiliary main are fitted with non-return valves and the header has two pop safety valves, one set for 110 pounds and the other for 115 pounds, the demands for steam being very intermittent, so that the pop valves serve as a warning to the firemen as well as a preventive of too high a pressure.

The exhaust steam from the engine room and the pumps in the boiler room is collected in a 10-inch line which carries it to a 1,000-horse-power Wainwright feed-water heater, built by the Taunton Locomotive Works. This was installed under a guarantee to heat 30,000 pounds of water per hour within 8 degrees of the steam temperature. It is not provided with a by-pass, but all the steam has to pass through it, and the exhaust main beyond subdivides into two 7-inch pipes, one leading to an exhaust head above the roof and the other to a special terminal submerged in the hot well about 1 inch below the water level. Each 7-inch branch has a stop valve. The hot well was described in connection with the chimney, in the issue mentioned, and consists of a four compartment concrete-steel basin resting on the chimney foundation, the compartments being separated by baffles and being respectively the receiving end, the oil skimming chamber, the settling chamber and the pumping chamber. The exhaust terminal is a pan of ¼-inch wrought iron, 2x3 feet in size, with 2½-inch sides turned downward. In the sides there are 62 1¼-inch holes spaced on 1¾-inch centers, and the total area of the holes aggregates double that of the exhaust pipe. The hot well will thus receive the condensation in the exhaust pipes and of such of the exhaust steam as will become condensed in issuing through the holes in the terminal box; the well also receives the water from the various tank heating coils in the factory and the exhaust from factory steam pumps, except as this is required for warming in winter.

The feed water is drawn from the hot well so far as possible, and additional fresh water is obtained from the city mains. There are three boiler feed pumps installed, built by the Buffalo Steam Pump Company, one for the 150-pound system and the others for the 100-pound system. They are, however, cross-connected and may all draw from the hot-well and deliver to the auxiliary main and vice-versa. The pumps for the higher pressure discharge through the feed-water heater on the way to the boilers. One of the latter pumps is arranged to receive the discharge from the low-pressure pump, working in tandem with it in delivering to those boilers working under the higher pressure. The two main feed lines are carried across the boilers as indicated in the drawings, and the interesting manner in which the connections to the drums are made is there shown. The 100-pound feed piping is provided with non-return valves to protect it against the higher pressure system. The high-pressure feed pipes are painted red; the low-pressure, white; and the exhaust, black.

The water supply for general cooling in factory and refrigerating apparatus is obtained by means of the air lift from three driven wells on the premises, the wells being located in the corners of a triangle, the shortest distance between any two being about 75 feet. One well is 500 feet deep and two 300 feet, and all are 8 inches in diameter to rock and 7 inches through rock. The air lift apparatus was furnished by the Pneumatic Engineering Company, of New York, and consists of two steam-driven, central crank and double flywheel, Rand Drill Company air compressors automatically regulated to maintain the desired pressure in two air reservoirs in the engine room.

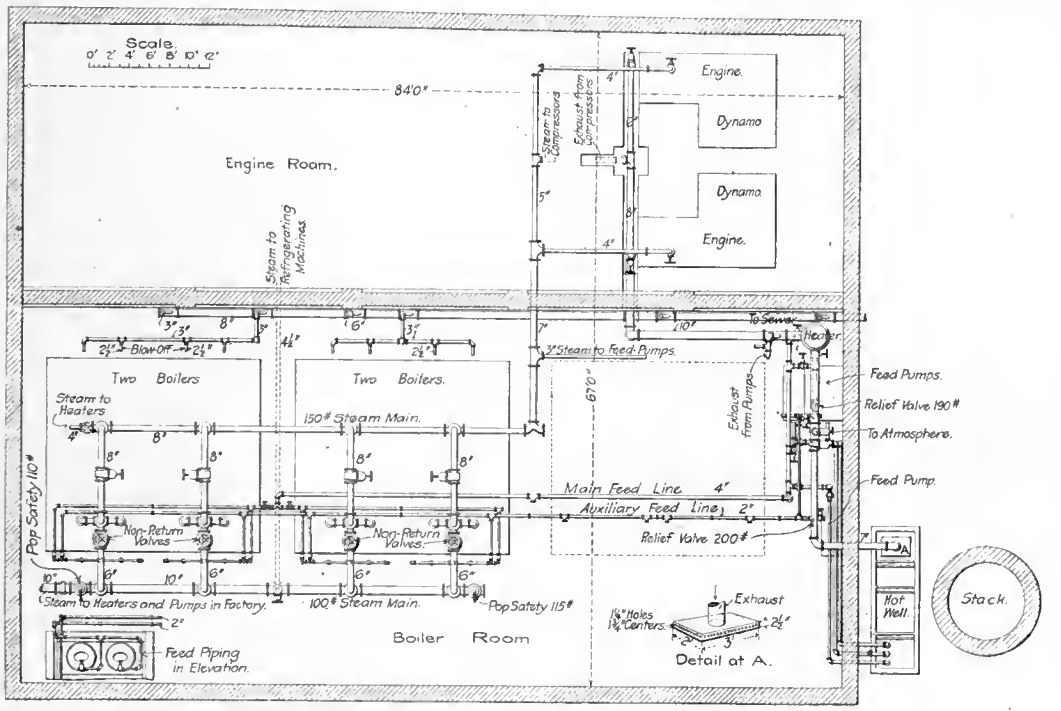
One compressor is operated ordinarily to compress to 20 pounds for factory purposes, and the other, drawing from the 20-pound pressure reservoir to compress to 110 pounds for the air lift. The air reservoirs are 3 feet in diameter and 8½ feet high. The water is delivered into two tanks in the factory basement and pumped therefrom by a 300-gallon double-acting Stilwell-Bierce & Smith-Vaile triplex pump. In connection with this system are three storage tanks on the fourth floor, and the water can be pumped to these for a gravity supply to the factory.

In the electric generating equipment compound non-condensing engines and 230-volt generators are employed, both light and power being supplied at this pressure. The engines are 9½ and 17x12 inches in cylinder dimensions, made by the Phoenix Iron Works Company, and the generators direct-connected Bullock machines rated at 283 amperes at 275 revolutions per minute. The feeders are controlled from a five-panel switchboard, two panels for the generator connections, one for power, one for power in the power house, including power-house lighting and the motor for the stoker blower, and the fifth for light. The generator switches are three-pole single-throw, thus including the equalizer connection with the main switch, while the feeder switches are double-pole. The feeders, as well as the generator leads, have circuit breakers. Stanley indicating instruments are used, and Thomson recording wattmeters are provided on the different main feeders, both for light and for power. The board was built and installed by the General Incandescent Arc Light Company.

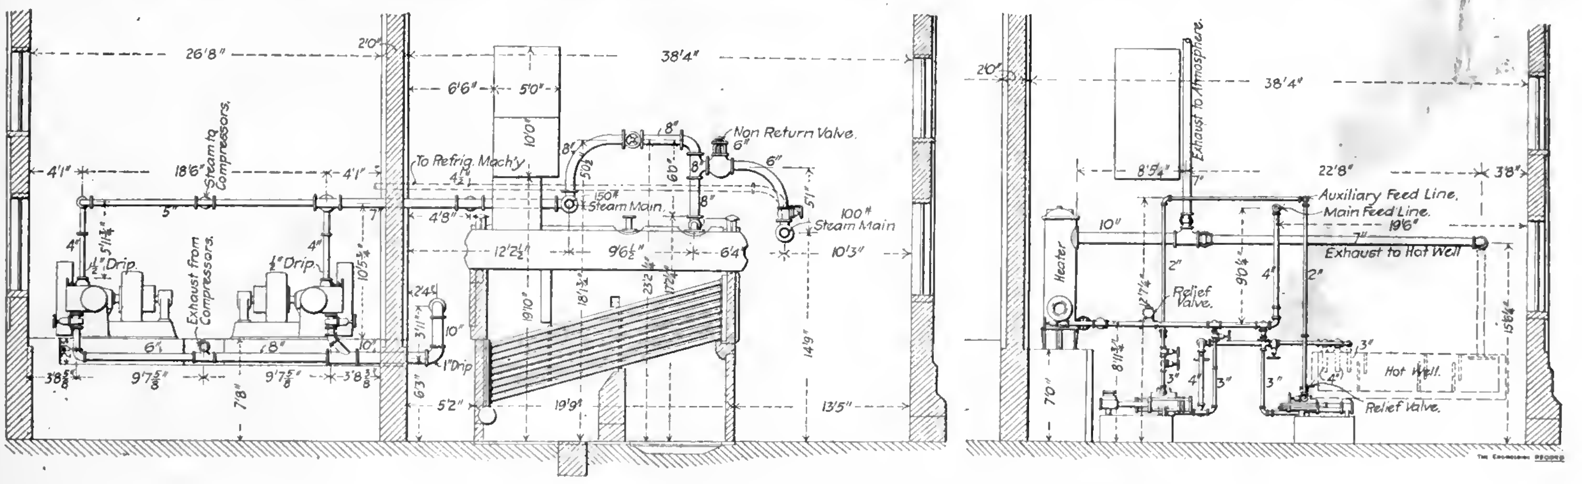
For refrigeration, the ammonia absorption type of apparatus has been installed, and the plant has a capacity of 120 tons of refrigeration. The installation, which was made by the Isbell-Porter Company, of Newark, is in duplicate, consisting of two generators, two absorbers, four condensers, two rectifiers and two ammonia and two brine circulating pumps, the pumps being furnished by the Foster Pump Works, of Brooklyn. The brine cooler is also located in the engine room, and the brine circulating system consists of a 5-inch circuit passing through the four stories of the factory ell connecting with a tank on the fourth floor. The brine is passed through lard coolers on the second floor, the piping to these coolers being on a shunt controlled, as desired, by a back pressure valve in the loop or shunt. On the fourth floor are a number of chill rooms from which the brine passes into the brine tank and thence back to the brine cooler in the engine room. The brine tank has also a connection from the main brine pipe in the fourth story, this connection likewise fitted with a back-pressure valve for bypassing the chill rooms.

Throughout the factory, as already stated, a large amount of pumping is required, involving some 5 miles of piping. The pumping units are largely 150 and 250-gallon Foster rotary pumps driven through speed reducing gearing by Sprague motors. There are also 10 steam actuated pumps, of both the Stilwell-Bierce & Smith-Vaile and Worthington type, where varying quantities of pumpage are desired at different times. There are three freight electric elevators running through the building, of 2,500 pounds capacity at 75 feet per minute, built by the Baltimore Machine Works. On account of the amount of moisture evolved in the different processes, the electric wiring is double-braided and waterproof sockets are used. The factory building is protected against fire by the Grinnell sprinkler system with a 13,500-gallon roof storage tank supplied by a 6-inch main from the city water system, which has a pressure sufficient to fill the tank.

The entire equipment of the factory was designed by Mr. Henry Floy, of New York City, and installed under the direction of Messrs. W. A. Gordon and C. E. Breckenridge, his assistant and inspector, respectively. The Structural Engineering Company, of New York, was the architect for the building.



PLAN OF POWER HOUSE.



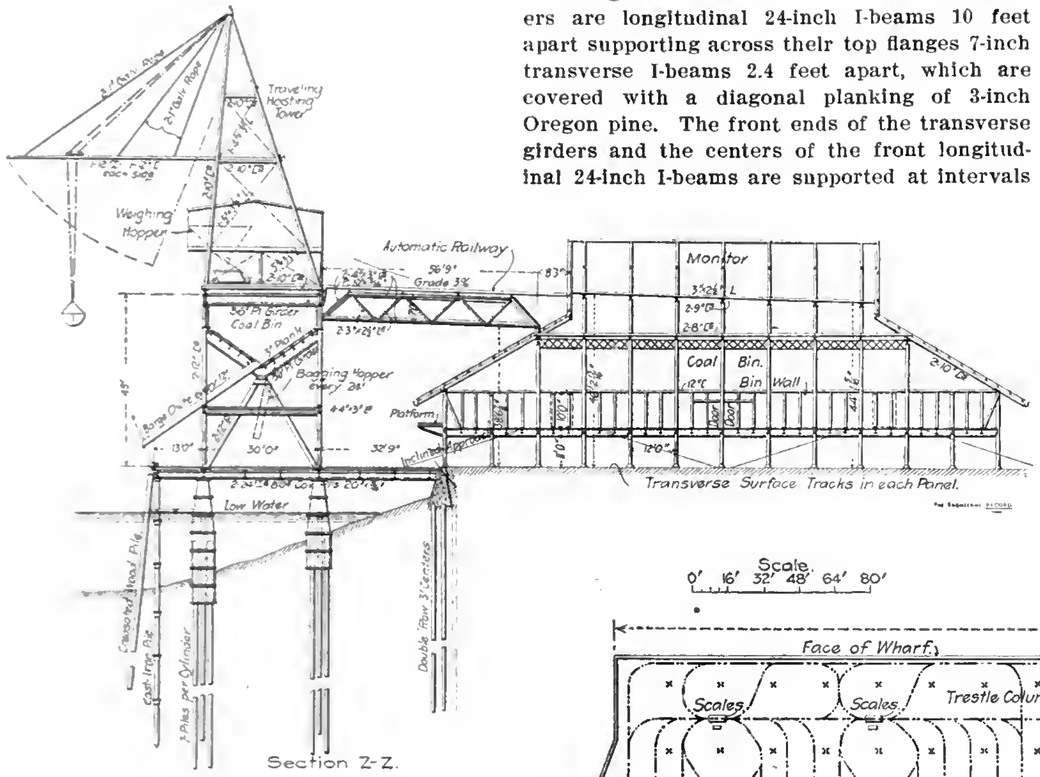
CROSS-SECTIONS OF POWER HOUSE, CENTRAL LARD COMPANY'S WORKS.

The Sangley Point Coaling Plant.

There is now under construction for the United States Government, a naval coal depot at Sangley Point, Manila Bay, Philippine Islands. It is designed for the storage and handling of large quantities of coal for naval and other vessels, and includes a dredged approach from the bay, a large iron wharf, the coal sheds, handling and weighing apparatus, power plant and fire service. The general plans and specifications were prepared by the Bureau of Equipment, Navy Department, Washington, Rear-Admiral R. B. Bradford, Chief of Bureau, and bidders were invited to present details to conform to the requirements. The type of sheds and system of operation proposed in the specifications were retained, but special details of foundations and structural iron work were submitted and approved and the general contract was awarded to The Atlantic, Gulf & Pacific Company, engineers and contractors, New York, for a total price of about $553,000, including the coal handling plant and operating machinery which is installed by the C. W. Hunt Company according to one of their standard systems.

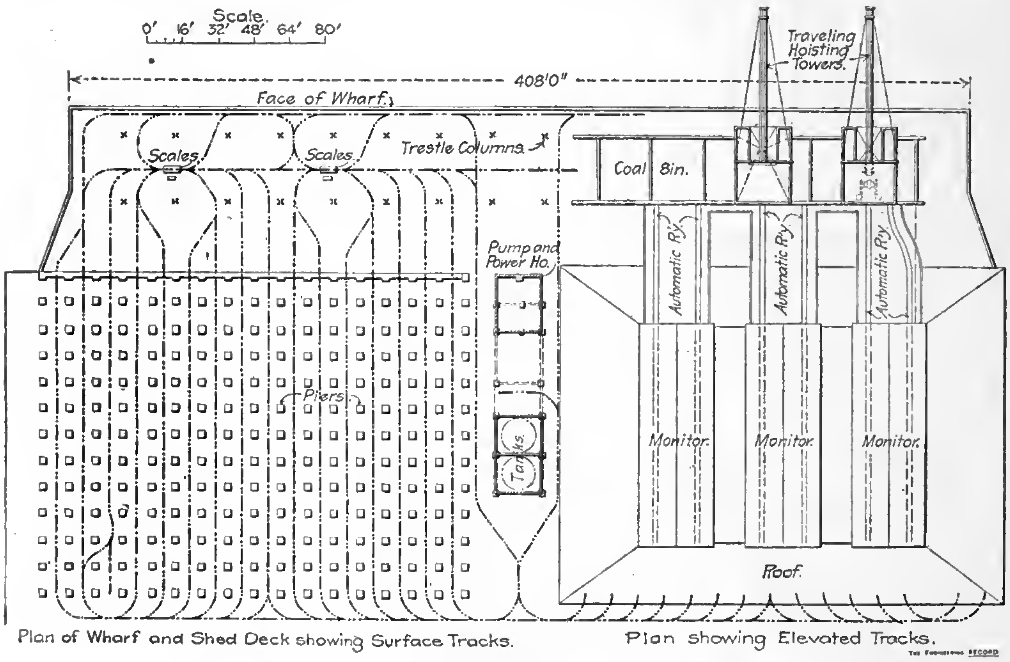
The magnitude and character of the work is indicated by the quantities involved, which include 40,000 yards of dredging, 25,000 yards of filling and grading, 3,236 piles, 222,000 feet timber, 7,246 yards of concrete, about 5,500,000 pounds structural steel, 1,200,000 pounds cast iron piles and pile cylinders, $100,000 worth of machinery and an $11,000 fire and power plant.

The plant is proportioned for the storage in sheds of 25,000 tons of coal and of 2,500 tons in open bins on the wharf front, for simultaneously unloading 50 tons of coal per hour from each of two vessels or lighters, and for transferring, storing, distributing or reloading the coal at an equal speed. The bottom in front of the wharf will be dredged to a uniform depth of 20 feet and width of 50 feet. The wharf has a front of 410 feet and a depth of 75 feet, and has a floor of pine plank on steel beams and girders supported 12 feet above low water on iron and concrete piers and piles. The shore side of the wharf is practically continuous with the discharge tracks under the coal sheds, which extend 150 feet farther back from the shore. A track 45 feet high and 30 feet wide extends across the front of the wharf parallel with the shore line and on it there are two traveling hoisting towers with movable booms which project 40 feet beyond the face of the wharf. There are two 193½ x 145½-foot two-story coal sheds, 46½ feet apart in the clear,



which are connected with the tower track by elevated lattice girder bridges of about 56 feet span. The two sheds are duplicates, about 59 feet in extreme height above the wharf floor and are built entirely of steel and concrete. Coal is delivered to them on tracks in the monitors, is stored on the second floor and is discharged through valves in the floor to cars on a system of tracks at the wharf level, by which it can be taken to any part of the wharf and transferred or delivered to vessels. Between the sheds is a steel and concrete house for the fire pumps and boilers, and back of the house is a twin tank tower of 50,000 gallons capacity. The arrangement of the plant, location of tracks and operation of tower hoists are indicated on the general plan and sections of the wharf and coal sheds. Coal is unloaded from ships or lighters by clam-shell buckets suspended from trolleys on the tower booms; is hoisted up, traversed back over the wharf, dumped in a hopper and thence into dump cars. The dump car stands on a weighing platform, and after weighing, can dump the coal into the wharf bin. Usually, however, the dump car runs by gravity on one of twelve tracks at right angles to the tower track, which extend through the monitors of the coal sheds. As the cars descend into the sheds they raise attached counterweights and when they are dumped at any required position the counterweights return the cars automatically to the foot of the tower ready for another load. In the floor of each coal shed there are 192 24-inch valves through which the coal can be drawn into surface cars in the lower story of the sheds, and thence transferred to any point on the dock front to be loaded into ships by the traveling towers, or to be used for filling the wharf bin. The contents of the wharf bin can be loaded directly through chutes into vessels alongside, or can be discharged into cars on the surface tracks and transferred.

The wharf is mainly supported on cylinder piers 24 feet apart in two longitudinal rows 30 feet apart. The front row of piers is 13 feet back of and parallel to the face of the wharf and the rear row is 30 feet from the face of the bulkhead wall under the front of the coal shed. The piers support on their center lines, transverse girders made of pairs of 24-inch 80-pound I-beams and 20 x ¾-inch cover plates 75 feet long over all. Web-connected to the girders are longitudinal 24-inch I-beams 10 feet apart supporting across their top flanges 7-inch transverse I-beams 2.4 feet apart, which are covered with a diagonal planking of 3-inch Oregon pine. The front ends of the transverse girders and the centers of the front longitudinal 24-inch I-beams are supported at intervals



The Naval Coaling Plant at Sangley Point, P. I.

of 12 feet by cast-iron sectional piles about 12½ inches in outside diameter and 70 feet long. They are made as shown in the detail drawing, in 12-foot sections, with turned hub and spigot joints locked together with through bolts. The lower ends are fitted with driving points and the upper ends are capped with cast-iron seats for the beams and girders. The former have vertical lugs to receive connection bolts through the beam webs, as shown, and the latter have horizontal base plates on which the bottom flanges of the girders are bolted. Both have vertical lugs for the connection pins of the 2-inch X-brace rods in the vertical plane between two lines of longitudinal struts 8 feet apart, which connect the tops of the piles above low water. The piles are strengthened by two 30-pound rails inside and are filled with 1:5 Portland cement mortar. To the 24-inch longitudinal girder in the face of the wharf are secured by 3 x ¾-inch U-straps the tops of inclined creosoted fender piles 6 feet apart on centers.

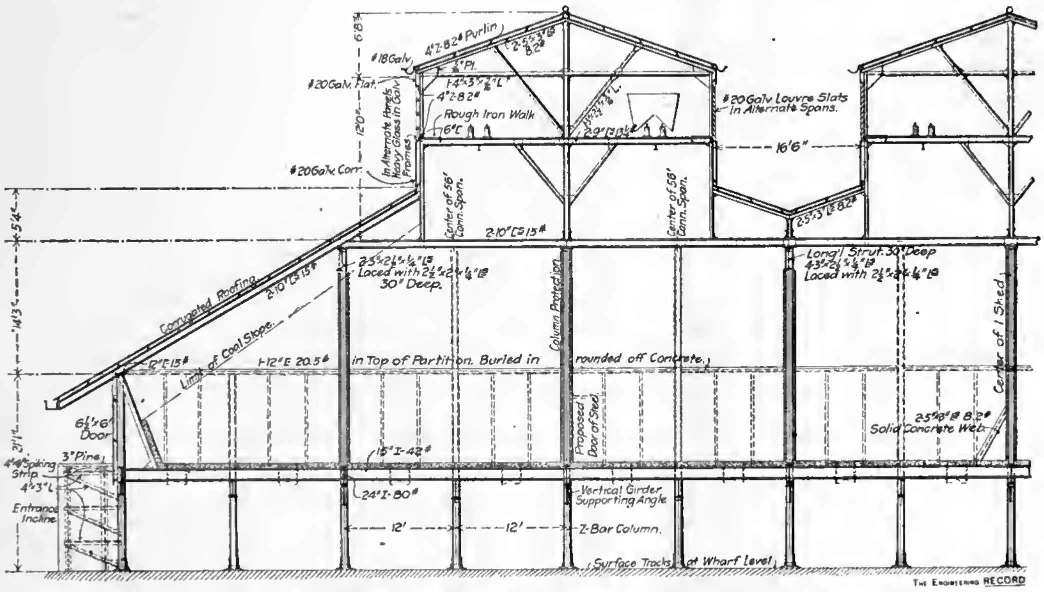
In each of the main wharf piers there are seven Oregon pine piles driven to 1-inch penetration under a 20-foot blow of a 2,000-pound hammer and calculated for maximum loads of 15 tons each. Six of the piles are cut off 5 feet below low water, the center one is cut off 6 feet higher, and all are enclosed in a sectional cast-iron shell filled with 1:2½:5 Portland cement concrete. The shells extend about 9 feet below the bottom of the bay for protection against the teredo, and are made up of flanged sections 4 feet 8 inches long, fastened together with 1-inch galvanized iron bolts about 12 inches apart. The shells are all one inch thick and the lower sections are cylinders 6 feet in diameter inside, while the three upper sections taper to a diameter of 3 feet at the top. Radial vertical lugs are cast on the foot of the second section from the top to receive the connection pins for the diagonal struts which brace the outer row of piers with the cast-iron piles in the face of the wharf. The concrete filling is crowned up an inch or two above the top flange of the shell and supports the transverse girders directly on a base plate bedded on concrete; only the bulkhead wall of the coal sheds supports the shore ends of the transverse girders. It is 10 feet high, 5¼ feet thick at the base, and 12 inches thick on top, battered on both sides and stiffened with buttresses 6 feet wide at the foot and 12 feet apart on centers. The wall rests on two rows of piles with two extra piles under each buttress.

The main piers of the wharf support on their centers the vertical posts of the steel trestle for the tower track. The bents are transversely braced, as shown in the sectional elevation of the wharf, and are connected longitudinally by two lines of horizontal plate girders. In the upper part of the trestle there is a coal bin about 22 feet clear of the wharf. This bin is fitted with swinging barge and bagging chutes 12 and 24 feet apart, respectively, and is connected with the upper parts of the coal sheds by lattice girder deck spans which carry the automatic coal tracks. All bolts and bracing in the wharf up to a height of 8 feet above low water level are galvanized. The minimum thickness of the structural steel is ⅜-inch, except below high water, where it is 9/16 inch, all sections being made thus extra thick to allow for loss by corrosion. The wharf is designed for a wind pressure of 50 pounds per square foot of exposed surface and for a uniformly distributed load of 350 pounds per square foot, besides the weights of towers, hoppers, coal bins, etc. The steel is designed with a factor of safety of 4, and the fender piles and walling pieces are creosoted.

The coal sheds are twin rectangular steel structures symmetrical with the transverse center line of the dock. They are each 193½ feet wide, parallel with the wharf front, and 145½ feet long, and are very simply constructed with numerous steel columns, beams and struts, without trusses or heavy girders. Under each shed there are thirteen longitudinal and seventeen transverse rows of columns 12 feet apart on centers in both directions. Each column has a separate pyramidal concrete pier 3 feet square on top and 10 feet high, with a pile foundation. Most of the piers have four piles and are 6 feet square at the base. Special piers have six or eight piles and there are altogether 2,480 piles under both sheds. Between the piers the ground is filled in up to the column bases to make a solid first floor under the sheds at the level of the wharf deck.

The columns in the coal sheds are each made with a web plate and four Z-bars and support directly the floor and roof beams and the monitor frames. Where the columns are in contact with the earth filling they are protected by concrete on wire lathing. Each row of columns which is transverse to the wharf front carries a line of 20-inch 65-pound or 24-inch 80-pound I-beam girders, which are connected to them by web angles and are seated on shelf angles with horizontal flanges reinforced by vertical distributing angles. These girders carry lines of 15-inch 45-pound I-beams 4 feet apart on centers, which are two panels long, are web connected to the girders at their ends and at their centers rest across the top flanges of the intermediate girders. The top flanges of the transverse beams are covered by a slab of 1:2½:5 Portland cement concrete 5 inches thick with a steel reinforcement embedded in it 2 inches above the bottom and covered with a granolithic surface 1 inch thick. The steel reinforcement consists of a galvanized wire netting with meshes 4 inches wide in both directions. In the direction of the stress the wires are No. 3 gauge, and in the opposite direction they are No. 10 gauge, electrically welded at all intersections. The concrete slabs thus formed bear the weight of the coal and were tested satisfactorily under direction of Mr. Felix Freyhold, engineer of the Bureau of Equipment. The electrically welded netting with different size rods in longitudinal and transverse directions is manufactured specially by the Clinton Wire Cloth Company, New York, and has the additional advantage that it can be procured in continuous lengths over 8 feet wide and 200 feet long, thus simplifying the splices and making economical laying.

The coal floor occupies the whole area of the coal shed and is about 12 feet high from the ground to the upper side of its floor. It has a capacity of 25,000 tons when filled to the maximum depth of 20 feet. The sides are inclined about 5:13 from the vertical and are constructed of reinforced concrete slabs like those in the floor, which are supported on inclined members made of two 6x4-inch angles riveted to the tops of the longitudinal beams and to a 12-inch wall-channel with its web in the plane of the rafter beam. Each coal bin is divided in four equal chambers by center longitudinal and transverse partitions 10 feet high, having double walls 3 inches thick, one on each side of the columns on the center lines of the building. The framework of the partition consists of a single 12-inch horizontal channel on top and 8-inch vertical I-beams, 4 feet apart. The 12-inch channel is protected by a convex layer of concrete in which it is embedded.



HALF-TRANSVERSE SECTION OF ONE OF THE COAL SHEDS.

Steel doors in the sides of the bin give access to it and the intermediate columns which pass through it are protected with concrete jackets. The coal is supported directly by the horizontal beams and girders, and as there is no horizontal thrust except on the low side walls, there is no lateral or horizontal bracing. About 23 feet above the floor of the bin there are beams composed of two 10-inch channels across the tops of the longitudinal columns to support the monitor frames. The monitor frames are built of channels and angles with riveted connections, and have horizontal transverse beams to support the wooden stringers of the inclined coal - delivering tracks. There are two tracks in each monitor and under the center of each track there is an I-beam carrying a pair of trolleys to support a movable deflection board which can be moved from place to place to receive the coal from a car in any position.

The three monitors in each shed occupy a total area of about 128x98 feet, on all four sides of which the hipped roof slopes uniformly to the eaves, which overhang the wall columns about 7 feet. Between the monitors there are valleys 16½ feet wide with flat slopes supported on pairs of 5x3-inch angles. In the center of each valley a space about 14 inches wide is filled solid with concrete flush with the roof surface to form a gutter pitched to the hip roof at each end of the monitor. All purlins in the main rafters, monitors and valleys are 4x3x3-inch Z-bars 4 feet apart. Horizontal Z-bars, like the purlins, are attached to the outer faces of the wall columns and the walls and roofs are covered with No. 20 galvanized corrugated iron, lapped two corrugations at joints. The roof leaders are 8 inches in diameter, made of No. 18 galvanized iron, and discharge into 12-inch glazed terra-cotta drain pipes emptying into the bay at least 30 feet from the face of the shed. The monitors have alternate side panels of glazed windows and galvanized iron louvres.

The outer solid wall covering terminates 2 feet below the tops of the columns and the remaining space is filled with small panels, every third one of which is movable so that it can be opened for ventilation. There is an exterior vertical roller-hung door to each division of the coal bin and two doors to each division facing the wharf, all of them having inside flash boards to keep the coal away from them. Inclined planes 40 feet long with steel frames and plank floors give access to the side doors from the surface of the ground, so that coal may be transported over them by hand if necessary. There are no hopper bottoms in the coal floor, but in the center of each 12x12-foot panel between columns there is a 24-inch double revolving floor valve which can be operated by one man and will draw off all but a very small quantity of coal which can, if necessary, be easily shoveled or scraped into the valves by men on the floor when the latter is nearly empty.

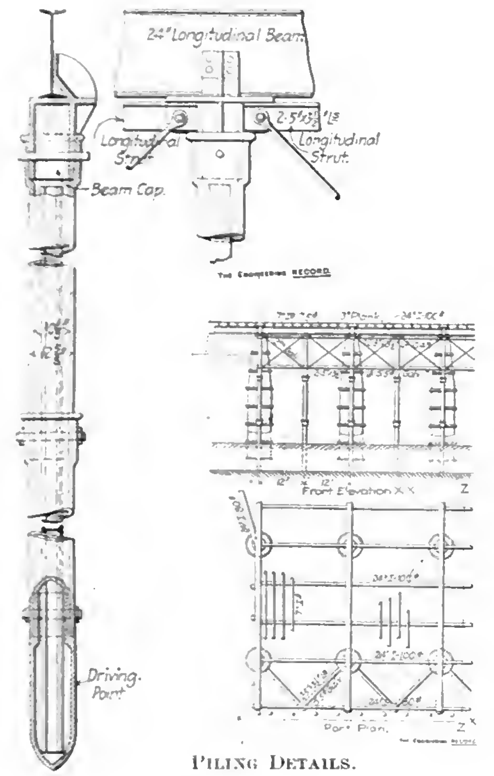
Vertical galvanized iron pipes 4 inches in diameter and 24 feet apart in both directions extend from the floor level to above the top of the maximum slope of the coal on the floor. They are pierced with ½-inch holes 6 inches apart, and both ends are capped and arranged to be accessible for testing, examination and cleaning. In each pipe is suspended a mechanical thermostat of open circuit type connected up to operate a danger signal in the custodian's house.

The coal handling plant includes two traveling steeple towers each with separate hoisting and traversing engines designed for 160 pounds steam pressure, 55-foot boom with 1-ton buckets of a loading or unloading capacity of 50 tons per hour and a 10-ton hopper with chute for loading automatic cars. All the tower machinery is housed in a shelter built of No. 20 galvanized corrugated iron. There are twelve automatic railways, four two-ton automatic dumping cars with oak bodies, lined with steel and mounted on a flexible wheel base; two automatic railway platform track scales, 7,200 feet of sectional track, 90 one, two and three-way switches and five two-ton industrial railway scales. There are also 36 one-ton coal tubs, 15 half-ton lever tubs, 6 bag trays, 36 one-ton four-wheel flat-top cars, and 36 1½-yard tip-cars.

Between the coal sheds is located a pump and power house about 22 feet wide and 50 feet long, with concrete walls and roof enclosing a steel frame supported on 32 piles driven in clusters of four and surmounted with concrete piers as for the coal sheds. Adjacent to the power house is a double steel tower with elevated fresh water storage tanks of 50,000 gallons combined capacity. In the power house are installed boilers and a 6x5¾x6-inch duplex pump with a capacity of pumping 100 gallons of fresh water per minute from boats for the boiler supply. There is also a 12x8½x12-inch duplex pump for fire pressure. It has an

8-inch suction pipe with strainer head in the bay and delivers into a 6-inch cast iron main laid around the outer walls of the coal sheds. It is connected to eight 2½-inch hydrants placed opposite doorways and fitted with couplings for standard navy hose connections. In each shed there is one 4-inch fire main along the wall of each outside monitor with valves and hose connections 75 feet apart. A similar 4-inch main is laid along the face of the wharf inside the guard timbers.

Materials are shipped from this country to Manila on the U. S. colliers and the work is erected by the Atlantic, Gulf & Pacific Company, the American Bridge Company being subcontractors for the structural steel work and the C. W. Hunt Company for the coal-handling machinery.



Piling Details.

The Dual Water Supply of Calcutta.

Calcutta has long been noted among engineers as possessing two distinct and extensive systems of water-works, made necessary by the peculiar local conditions. It is built on the right bank of the River Hugli on land so flat that it is necessary to go 100 miles from the town to reach an elevation of 100 feet. The average annual rainfall is about 61½ inches, occurring mainly in June, July, August and September. The maximum monthly temperatures in the shade are from 76 to 95 degrees and the minimum from 55 to 79 degrees; the greatest range in the year is from about 44 to about 107 degrees. The water supply was drawn originally from the river and from tanks in which the rainwater was collected. In 1820 a pumping station was built which furnished river water to open brick channels running along the streets of a small part of the city, and this plant, with some extensions, sufficed until 1862. In that year works planned by the late W. Clark were authorized. The scheme, subsequently enlarged and modified, provided at first for the distribution through a pipe system of 3,000,000 to 4,500,000 imperial gallons of filtered water at an expenditure of $550,000 to $675,000. This was the commencement of the present works, which although long known in a general way to be of much interest, were never adequately described until the Institution of Civil Engineers recently published a paper concerning them, by Mr. Arthur Peirce. From this paper the following notes have been taken.

The construction of the original works was commenced in 1866-1867. They were designed to supply 6,000,000 imperial gallons of filtered water per day, to a population estimated at 400,000, or an average of 15 gallons per head per day. The actual cost of the work appears to have been about $3,300,000.

Intake-works were constructed on the river bank at Palta, about 14 miles above Calcutta, and practically beyond the influence of the brackish water brought in by the tide. Water is pumped from the river by three 50-horse-power beam-engines, into six masonry settling-tanks having a total capacity of 24¼ million imperial gallons. From these tanks the water gravitates, after settling, onto the filter-beds, twelve in number, which have a collective area of 240,000 square feet. After filtration the water is collected in a central well, and gravitates through a 42-inch cast-iron pipe, having an average fall of about 1 foot to the mile, to a second station at Tallah, some 12½ miles distant, and near the northern boundary of Calcutta. At Tallah the water is received into a covered reservoir of 1 million imperial gallons capacity, from which it is raised by pumping machinery and distributed. The distribution is effected by pumping directly into the mains, without intervention of raised reservoirs or stand-pipes, a direct pumping station being provided in the city to furnish sufficient pressure in certain districts. Its supply is taken from a 6¼-million gallon underground reservoir.

The growth of the population, together with the extension of the boundaries in 1888, led to a largely increased demand upon the works as originally carried out, and it was accordingly decided to augment the supply considerably. A new pumping station was erected at Palta, about ½ mile distant from the old station. Three 75-horse-power pumping engines were installed, and ample provision for settling purposes was obtained by the construction of four large "kutcha" or earthen settling-tanks, two 2,060 feet in length by 230 feet in width, and two of 2,060 feet by 355 feet, the whole having a total useful capacity of 82,750,000 imperial gallons. Twenty-four additional filter-beds were also constructed, each 200x100 feet, increasing the filter area by 480,000 square feet. To convey the increased supply of water to Calcutta, a new 48-inch cast-iron pipe, 66,000 feet in length, was laid between Palta and Tallah pumping stations. The works at the receiving station at Tallah were strengthened by the addition of two new pumping engines, whilst the reservoir accommodation was increased from 1 to 3 million imperial gallons. An additional pumping engine was erected at the old city pumping station, and a new station was erected at another point, where four beam-engines were fixed and an underground reservoir was constructed of 4,000,000 gallons capacity. For the supply of the southern suburbs still another new pumping station was built and fitted with two triple-expansion Worthington engines, with an underground reservoir of nearly 3,000,000 gallons capacity. These extensions were completed in 1891, and were designed and carried out by Mr. J. Kimber. Subsequent additional engines were set up at Tallah, but the system of supply remained unchanged.

The cost of the whole of the filtered-water works, up to March, 1899, amounted to about $15,000,000.

The six original settling-tanks are each 500 feet in length, 250 feet in width, and 7 to 9 feet in depth. They are constructed entirely of masonry, four of them being provided with a series of silt-catching pits, whilst the remaining two are plain. In practice no particular advantage is found to be gained by the use of the silt pits.

The new settling-tanks present more novel features; they are merely excavated in the soil, a poor sandy clay, and the banks are formed from the soil, puddling being dispensed with except upon the side of the tank next to the filter-beds. The other banks were formed by depositing the excavated material in layers of 1 foot thickness, and consolidating them with water. In September, 1888, towards the end of the rainy season, a breach occurred in the outer bank of one tank, and with the outrush of water some 50 feet of the bank was carried away. Two days later the bank between this tank and an adjoining one gave way, making a breach about 30 feet in length. After repairing these breaches steps were taken to prevent the erosion of the repaired banks by the action of the waves; strong bamboo piles were driven at the toe of the slope, and the bank was pitched with rough-dressed stone. Other portions of the banks are pitched at the water-level with bricks set on edge. The percolation from the tanks is remarkably small considering the nature of the soil, the ascertained loss in depth being only ¾ inch in 24 hours and of this 5/16 inch is accounted for by evaporation.

The original filter-beds consist of 1 foot of pebbles, ranging in size between that of a goose egg and that of a pea, overlaid with 4 inches of coarse sand, and topped with 2 feet 6 inches of fine river sand. On passing through the filtering media the water is collected in small cross-drains 4 inches square in cross-section, covered with tiles spaced to permit the water to enter the drain. The cross-drains in each filter deliver the water into a collecting-drain laid along the middle of the filter, and these drains in turn deliver into a collecting-well from which the water flows directly into the conduit-pipes. The new filter-beds consist of two courses of dry bricks properly spaced to permit the passage of the water, overlaid with 4 inches of coarse sand, and topped with 2 feet 6 inches of fine river-sand. The two systems of filters appear to work equally well so far as the filtration is concerned, but the new filters are to be preferred as being more simple and more cheaply constructed, and are more easily cleaned than the original filters. The minimum thickness of sand permitted, before replenishing, is 1 foot. The average rate of filtration which has been found to yield the most satisfactory results is 40 imperial gallons per square foot per day of 24 hours, the head of water varying between 3 and 20 inches. The filtrate is clear and bright excepting at the commencement of the rains, when an opalescent tinge is noticeable, which is probably due to iron and other compounds washed from the upper watershed by the first heavy rains. The number of bacteria in the filtered water now seldom exceeds 50 per cubic centimeter. The only suspicious feature in the bacteriological test is the continued presence of the bacillus *coli communis*, but the bacillus is common to most Indian surface-waters. In washing the dirty sand no mechanical washers are employed. The dirty sand is placed in masonry tanks measuring about 12x12x3 feet, and having false bottoms, under which water from the settling-tanks is introduced. An objectionable feature of this method of washing is that it necessitates men standing in the tanks to agitate the sand.

The two conduits between Palta and Tallah are 4 feet and 3 feet 6 inches in diamater and 66,000 feet in length, and work under heads of 12.2 feet and 9.5 feet respectively. They consist of cast-iron pipes with turned and bored joints. The calculated discharge in 24 hours of these pipes running full (by the Kutter formula, taking the value of n as 0.011), is:

3-ft. 6-in. pipe..........	7,640,000 imperial gallons
4-ft. pipe	12,616,000 " "
Total	20,256,000 " "

which approximates closely to the actual discharge.

The underground reservoirs at the distributing stations are filled during the night from Tallah pumping station, the water being pumped through what is known as the independent pumping-main, a pipe 2 feet 6 inches in diameter reserved for this purpose only. The engines at the distributing stations complete the distribution in the service mains. The distributing mains vary between 2 feet 6 inches and 9 inches in diameter, and parallel services between 6 inches and 3 inches diameter are provided for mains exceeding 1 foot in diameter. The total length of mains and services now in use in connection with the filtered supply is 315 miles.

Ferrule connections with the main are allowed to all pucca or masonry houses, the size of the ferrule varying according to the assessed annual valuation of the premises, or the gross annual rent less 10 per cent. in the case of rented premises. In the case of "bustees," or groups of native huts under one ownership, one or more connections were formerly allowed, according to the ratable value of the property, the taps being fixed in an open space accessible to all, but under the new Municipal Act of 1899 connections are only allowed with pucca or masonry houses. In other cases water is drawn from standposts fixed at frequent intervals in the public streets.

The present practice in Calcutta is to maintain a pressure equal to a head of about 60 feet at the distributing stations between 6 A. M. and 10 A. M. and between 3 P. M. and 6 P. M. In addition a low pressure, sufficient to serve the standposts, is maintained during the remaining day hours in the more thickly-populated portions of the town.

The average daily consumption of filtered water in the town and suburbs now amounts to 20,356,873 imperial gallons, which for a population estimated at 843,487 (including floating population in port and canals) gives an average of 24.1 gallons per head of population per day. Filtered water is not used for road-watering or sewer-flushing.

In addition to the supply to the town and suburbs, water is also supplied to the cantonment at Barrackpur and to the municipalities of Dum Dum, Cossipur, Chitpur and Manicktolla. The quantity of water so supplied is on an average about 300,000 gallons per day. Connections are not generally permitted, and the supply is drawn principally from standposts.

The nature and habits of the population, and the tropical climate, in Calcutta, together with the dense population in portions of the town, render an ample supply of pure water a necessity, if the ravages of disease common under such conditions are to be successfully combated. A supply of 24.1 imperial gallons of filtered water per head per day must, however, be considered an ample allowance for domestic purposes, as in addition to the filtered supply there is a copious supply of unfiltered water for use in road-watering and sewer and privy-flushing. The existing intermittent supply of filtered water is unsatisfactory and its distribution is defective. The lavish use of the water and the careless habits of the population, taps being constantly left open in all parts of the town, lead to considerable waste. Much of this waste is doubtless due to the fact that the supply is an intermittent one; the pressure being maintained for a few hours only during the day, the consumers leave the taps open to fill various receptacles. Another cause of waste is the state of some of the older mains and services laid in the town, which are believed to be unsound, but as an easy escape is provided by old sewers and drains, it is difficult to localize the leaks.

The average cost of the filtered water, including all charges, repayment of loans and interest, amounts to about 5 cents per 1,000 imperial gallons. The charges are met by levying a rate of 6 per cent. upon the assessed annual ratable values of properties assessed.

In addition to the filtered water supply, the town proper is in possession of a practically complete system for the supply of unfiltered water, which is used for road-watering, sewer and privy-flushing, watering gardens and fire-extinguishing. This supply, as in similar instances elsewhere of dual supplies, had a comparatively small beginning. It was proposed by the late Mr. W. Clark, M. Inst. C. E., in 1871, when the filtered water supply was fast becoming insufficient for the needs of the population. The scheme was eventually carried out, the old machinery and buildings used for the supply of the town prior to the introduction of the filtered supply being utilized for the purpose. Although the filtered supply was subsequently greatly increased, the idea of abandoning the unfiltered supply does not appear to have been considered; on the contrary, the old pumping machinery was replaced by two horizontal compound condensing engines, each capable of raising 211,000 gallons per hour. These engines have, in their turn, been replaced by four three-stage expansion Worthington engines, each capable of raising 380,000 gallons per hour against a head of 140 feet. The system of pipes in connection with this supply is being extended into every sewered street, and already there are 116 miles of pipes laid, varying in diameter between 4 feet and 3 inches. The water is pumped direct from the river and is delivered without any attempt at settlement or filtration. The average daily supply now amounts to 12,000,000 imperial gallons, and is ample and practically constant, extending to 20 hours per day.

Steam is supplied from four Babcock & Wilcox boilers fitted with mechanical stokers, and superheaters of the Babcock type. The amount of superheat obtained in ordinary working amounts to 137 degrees. Some difficulty was experienced in making the joint tight against the superheated steam, and cylinder-joints are now made with thin asbestos with brass wire-gauze insertion, steam-pipe flange-joints being made with corrugated brass rings. In the smaller steam-pipes flange-joints appear to be a necessity. The difficulty of lubrication was easily overcome by the use of a high-grade cylinder-oil. The water is pumped directly into the mains, without the intervention of stand-pipes or raised reservoirs. There are 3,898 hydrants fixed in the town, for purposes of road-watering, etc. The watering of roads is effected by means of a hose, the hydrants being spaced about 100 feet apart. Sewer-flushing is effected partly by automatic flushing-cisterns and partly by hose. Privies are flushed by means of waste-preventing cisterns.

The unfiltered water-supply has lately been extended to the added area, old machinery from the town station being utilized for the purpose. A new pumping station has been erected on the river bank and about 30 miles of pipe, varying between 2 feet 6 inches and 3 inches in diameter, have been laid in the streets which have been, or are to be, sewered. Two thousand hydrants are to be fixed upon these pipes for use in road-watering, sewer-flushing, fire extinguishing, etc. The supply at present amounts, on an average, to about 350,000 imperial gallons per day, which will be greatly increased when the drainage-works now in hand are completed. These works were carried out under the chief engineership of Mr. A. J. Hughes.

The capital sunk in the unfiltered water system amounted at the end of March, 1899, to $810,000. The cost of pumping the water for the year amounted to half a cent per 1,000 gallons.

In an inland town where ample water is available for filtering the adoption of a dual supply must always be open to question, but once it is adopted, even upon small scale, it is difficult to dispense with it. In Calcutta, owing to the exceedingly level nature of the land, the levels of the streets vary only to the extent of 3 or 4 feet, the sewers have but little fall, and a large quantity of water is required to flush them efficiently. The filtered water has to be brought from a distance, filtered and pumped several times before use, and were it used for flushing purposes the supply would, for economic reasons, have to be curtailed. A large quantity of water is also required for road-watering, as little or no rain falls between the months of October and June. River water is easily obtained all the year round, is drawn from a central point, and costs 1.68 cents per 1,000 imperial gallons, as compared with 5 cents for filtered water. The principal objections to the system lie in the cost of providing and maintaining separate systems of mains and pumping stations, and the distribution, in a tropical climate, of water that is unfit for drinking purposes and is at times charged with cholera and other dangerous water-borne bacilli. The latter objection is a most serious one when it is considered that the bulk of the native population are too simple and uneducated to realize the danger likely to arise from the use of such water.

The Adjustment of Water Rates.

The San Antonio, Tex., Water-Works Company is operating under a State charter expiring in 1933, a municipal franchise for the use of streets which run ten years longer, and a municipal contract for public and private water supplies which will terminate on August 1, 1903. The proximity of the last date, the need of extensive additions to the company's plant, and the desire of the city authorities to establish a new schedule of rates led to a correspondence lasting some months between the parties to the contract. While both sides were conducting the negotiations in a friendly spirit it seemed impossible for them to reach a mutually satisfactory agreement unaided, and the city and company accordingly united in requesting Mr. Chester B. Davis, M. Am. Soc. C. E., of New York to assist them in establishing a just schedule of rates and form a contract for a period of ten years. He accordingly made an examination of the plant, the requirements of the community as to water, the methods of managing the company and the improvements and extensions of the plant which the conditions demanded. On the basis of this information he estimated the value of the plant and its legitimate expenses of operation, and prepared a form of contract which was immediately signed by the city and company, thus bringing to a sudden conclusion a controversy which had lasted eighteen months and was still as far as ever from settlement when he was retained. This unusual and highly desirable result makes a study of some features of the report a matter of much interest.

The company was found to be conservatively and economically managed, and the plant well built and capable of performing satisfactorily the service for which it was intended except in a few particulars. One of these defects is a lack of sufficient storage in the distributing reservoir, which does not hold more than a third of the present daily supply. The most serious defect is in the fire hydrants, which are not only altogether too few in number but also of the single-nozzle type which is inadequate to the service of such a city. The scarcity of such hydrants is shown to be a poor business policy, for they cost but $45 or thereabout in place and last indefinitely, while good hose costs about 95 cents per foot and lasts only five years or so. If the hydrants are spaced far apart, long lines of expensive hose are required and the available pressures at the play pipes are much lower than with shorter hose lines. Accordingly the new contract provides on new mains for double-nozzle hydrants at least every 250 feet within the fire limits and at least every 500 feet outside this boundary, and the hydrants in the high districts are to have steamer nozzles as well. On the old mains similar hydrants are to be placed whenever ordered by the city between the old hydrants, although not closer than 125 and 250 feet inside and outside the fire limits respectively, and the old hydrants are to be replaced by better types when ordered by the city, the cost of the work in all such cases to be borne by the city and the cost of materials by the company. The latter also agrees to put in mains of suitable size for fire protection as well as domestic supply and to have them well cross-connected.

While in these and other respects the company is to improve its plant, the city agrees to much better measures for preventing waste, which is excessive. A supply of 80 gallons per capita or about 5,000,000 gallons daily is ample, Mr. Davis reports, while the works are now called upon to supply 8,000,000 to 12,000,000 gallons. This excessive supply is the subject of one of the most interesting portions of the report. It is first shown that its effect is practically to exhaust the present sources of supply and, if unchecked, render it necessary to build very costly new works. As all the water must be pumped the waste is also causing a constant large addition to the operating expenses. Still another effect is felt in the distributing pipes, which are ample, when a reasonable draft for domestic supply is satisfied, to furnish plenty of water for fire protection. If the normal draft is twice as great as necessary, the fire streams are reduced in volume unless very costly new mains are laid. "About one-half of the fuel burned under the boilers and in effect fully one-third of the capacity of the entire plant," Mr. Davis says, "is absolutely wasted and thrown away, it serving no useful purpose; this third has involved the investment of a large sum of money, requires the collection each year from the consumers of water of a large and entirely unnecessary amount of money to pay the interest, the cost of maintenance, administration, operation, etc., besides paying a reasonable profit on all of this to the company as required by law."

The rather unusual position is taken in the report that it is the city's duty to check waste by exercising its police powers. It is stated thus in one place: "The municipality is bound from every fair consideration to take the initiative because it represents the consumers who do not waste and represents all who must pay for it, and more especially because it is the one way above all others which puts it in the position where it can most justly demand a revision of rates and bring about the very minimum cost of water for public and individual use." The report advises the use of meters on large services and also on small services where much waste occurs, but it also advocates inspection, as another quotation will show. "The city's sanitary inspectors and its police can maintain the constant inspection needed at little or no added expense, and since the consumer or the city or both must pay every legitimate item of operating expense, they must really pay for this waste-detection inspector, even if they compel the company to employ and direct the inspectors. It is the city's duty to maintain this inspection and to stop the unnecessary waste, which it can do at a less annual cost to the consumer." It is not apparent that this idea has been embodied in the contract, however, unless the following clause is held to cover it: "That the party of the first part agrees to protect by ordinance the works, fixtures and other property belonging to or controlled by the party of the second part, from interference, wrongful use, injury, carelessness or waste on the part of third persons." The contract gives the company the right to maintain a system of house-to-house inspection and to install meters where water is wasted or used for more fixtures than were stated by the consumer in applying for a supply.

In preparing an estimate of just rates the following items were considered by Mr. Davis to embrace everything to be considered.

1. Administration expenses, including the bookkeeping and collection of accounts.
2. Operating expenses connected with the plant.
3. Maintenance expenses to keep the plant in condition to perform the service required of it.
4. Taxes, because if they are paid they must be earned.
5. Interest, the rate to be conservative and consistent with the locality and the influencing conditions, or it may be considered a part of the gross percentage of profit to be allowed on the plant and its operation in excess of the annual allowances.

Under this plan no allowance is made for improvement and extension expenditures or for depreciation, thus following the railway accounting systems. The expenses for services, mains, machinery and other improvements and extensions become a part of the construction account, which is a part of the total investment. The depreciation is included almost wholly under maintenance, a plan recommended in a recent paper by Mr. Price-Williams published by the Institution of Civil Engineers. Mr. Davis explains his reasons for employing it as follows: "The meaning of the word depreciation in this use is the decrease in value due to a deterioration, and as a rule those who use it in connection with work of construction misunderstand entirely its meaning, and they assume, what is almost always a mere guess, that it is a certain percentage of the value of a new plant, generally varying between 2 per cent. for the more enduring structures and an increasing percentage as the plant or structure is less enduring. Five per cent. annually is usually assumed as the extent of the depreciation of machinery. In truth, nothing of the sort happens with well cared for machinery, for it is properly repaired and maintained, and the maintenance expenditures keep it in proper and running order, long after the percentage depreciation theory would have it useless. It is true that there is a real depreciation in excess of the maintenance expenditures, but what it is in a composite plant like the one under consideration no one knows or can ever determine. A sum equaling a small fraction of one per cent. of the present value of the present plant, contributed annually to a fund which is compounded at 4 per cent. annually, will more than compensate for the actual depreciation in such a plant as the one under consideration, if it is maintained in a reasonable condition."

In estimating the value of the company's property all of the plant and its appurtenances in actual use and actually needed were included at what Mr. Davis considered a fair and reasonable price. Worn out, disused or unnecessary portions and land and rights acquired because of prospective value or need were not included. The actual physical condition of the parts of the plant as compared with new material and machinery, so long as they were reasonably performing their intended service, was not considered, but betterments and extensions imperatively needed to perform any services specified in contracts made before the new rates went into effect ought to be considered, Mr. Davis states. If the valuation were made for the purpose of purchasing the property, he states that it would be proper to make a deduction to represent the actual decreased value of the plant as compared with a new one. "In the one case it is the value, or the cost, of the plant to the owner, in serving his purposes, while on the other, it is the value to the purchaser as compared with the cost of duplicating it new."

As for the reasonable percentage of clear profit which the company should expect, the report is as follows: "I believe it would be outside the spirit of the law and unfair as well to reduce the rate of profit until it equalled the lowest rate of interest, say five or six per cent., on the best loans in the vicinity, because the money invested is not devoted to so conservative a use. Nor do I believe it just to ask the consumers to pay rates sufficient to provide dividends to the stockholders equalling those coming from well-managed successful manufacturing and ordinary commercial occupations, which may easily reach twelve or a greater percentage, because the business of a water company does not involve equal risks. It is my opinion that if the rate is fixed between seven per cent. as the very minimum and ten per cent. maximum, on a reasonable value of the plant above all of the administration, operation and maintenance expenses and also taxes, it will be a fair and reasonable return to the company." The contract which was signed gives a profit of about eight per cent. on the basis of Mr. Davis' figures.

The Action of Bacteria Beds at Newbury, England, in reducing the sludge problem to a minimum, is described in a recent issue of "The Surveyor," substantially as follows: Up to December, 1899, the whole of the sewage was treated chemically. At that time one of the old precipitation tanks, 60x24x4 feet in size, was converted into an experimental bacteria bed by filling it up with furnace clinkers. The results were so satisfactory that two other tanks were converted in the following March, clean sifted shingle dug from a portion of the land at the works being used for filling. These two beds proved even more satisfactory than the clinker bed, so that after six months' working, the Main Drainage Committee was induced to construct a sufficient area of bacteria beds to treat the whole of the sewage. Accordingly five concrete tanks, each 60x24x5 feet, were constructed and filled with gravel. They were first charged on June 24, 1901, and have worked continuously ever since. They are worked on a six-hour cycle (*i. e.*, filled four times in twenty-four hours). The use of chemicals and the work of sludge-pressing ceased on the same day, the saving in these two items being over $1.460 per annum. The capacity of these gravel beds when first charged was about one-half the total cubical contents of the empty tanks; after a few days this shrunk to one-third, and at the end of three months to one-fifth, at which figure it has remained since. The effluent is passed over the land, and has proved satisfactory to the Thames Conservancy analyst. The beds receive only 264,000 gallons out of a total of 408,000 gallons per 24 hours.

Suspension Foot Bridge, Easton, Pa.

By John McNeal, Jr., Civil Engineer, Easton, Pa.

The numerous industries established near the western limits of the city of Easton, Pa., during the past few years, employing about two thousand men, opened the way, in the opinion of the Lehigh Bridge Company of that place, for a small investment in the form of a toll bridge across the Lehigh River, in the immediate vicinity of these works. The location decided upon for this bridge, made the design much out of the ordinary, consequently competitive designs were requested from several bridge companies and that presented in this article, submitted by the Boston Bridge Works of Boston, Mass., was accepted. Specifications and plans for the masonry substructure were prepared by the writer and the bridge erected under his supervision.

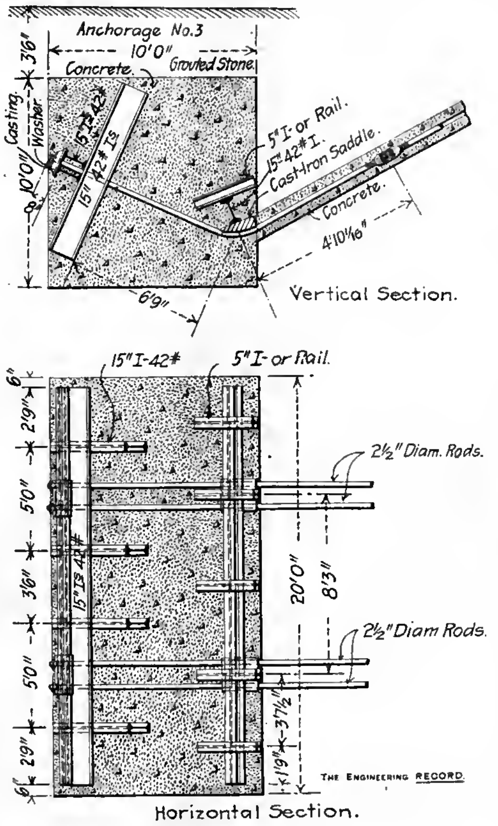
The bridge shown in the accompanying plans, connecting Easton proper with South Easton or the South Side, crosses the Lehigh River, the canal of the Lehigh Coal & Navigation Company and the Lehigh Valley Railroad, making the total length of the structure 668 feet. In order to avoid crossing Dock Street at the north end of the bridge, it was necessary to have four runs of steps to reach the grade of the street. The anchors for this end of the bridge were placed under the bed of Dock Street and the rods to which the cables were attached allowed to project just beyond the street line.

During the excavation for the anchor at the Dock Street end of the bridge, it was found necessary to change the original plan for this anchor, owing to the excessive amount of water encountered, which the gravelly soil allowed to seep through from the river. This change was made possible by making a bend in the anchor rods near the base and adding additional weight in the form of castings and I-beams to overcome the decrease in depth.

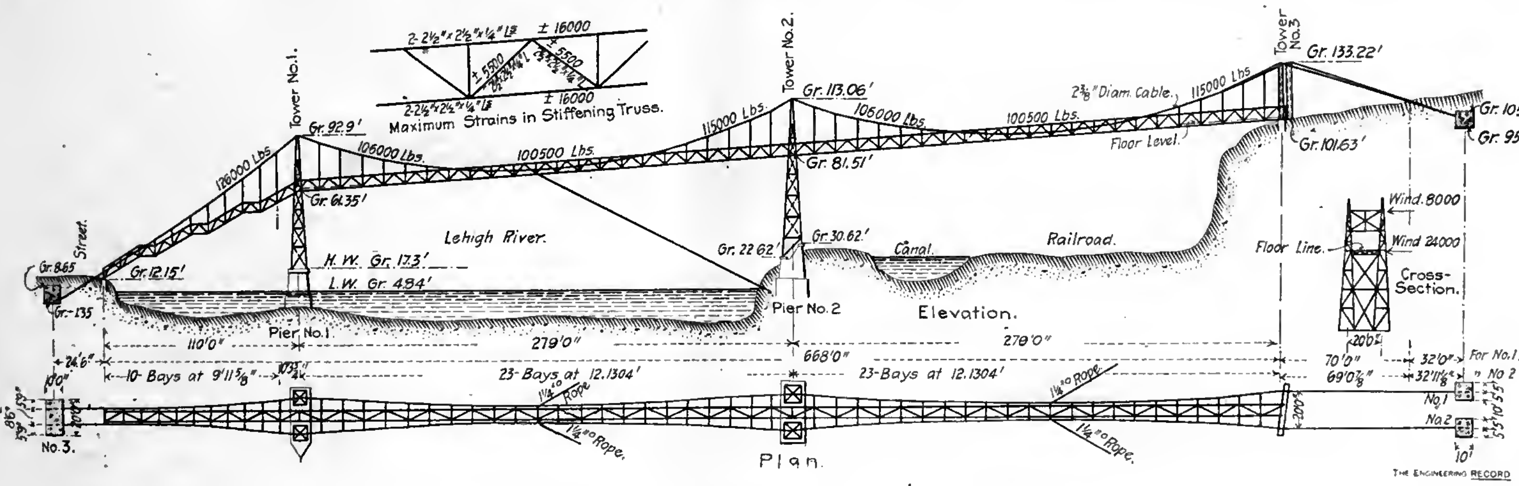
The anchors at the south end of the bridge were placed in a lot purchased by the company, just south of Glendon Avenue, and the cables

The main cables are composed of seven strands of galvanized steel wire, 19 wires to each strand, making a total diameter of 2⅜ inches. One and one-quarter-inch guys were also run from the middle points of the two long spans to anchors placed on the berm bank of the canal and on the sides of Glendon Avenue, at an angle of 45 degrees with the center line of the bridge. The main anchors, as well as the anchors for the guy lines, were imbedded in concrete, at a safe distance under the surface of the ground.

The stiffening truss is attached to the cables by means of hangers composed of ¾ inch round iron. The stiffening truss is composed of two



The Dock Street Anchorage.



The Suspension Foot Bridge at Easton, Pa.

carried above the street by means of a tower placed on the north side of the avenue, leaving a clear headway of 20 feet.

The bridge has three spans, one of 110 feet and two of 279 feet each, necessitating three towers; one in the Lehigh River, one on the berm bank of the canal and the one already mentioned on the north side of Glendon Avenue. The difference in elevation between the ends of the bridge is 89.48 feet. As already stated four runs of stairs are placed at the north end of the bridge leading to a point over the center of the river pier, and from this point to Glendon Avenue the grade of the bridge is about 7.2 per cent.

trusses of 2½x2½x¼-inch angles of the same section throughout, properly braced, in order to give the greatest possible stiffness. The stiffening truss is proportioned for a live load of 20 pounds per square foot, the cables and floor for a live load of 50 pounds per square foot and the floor itself for a live load of 80 pounds per square foot. The width of the footway from center to center of trusses is 6 feet.

On the two long spans, the low point of the cable is 24 feet 3 inches to the north of the center point, the reversed side of the cable being 1/10.

The following Eastonians are the directors of the Lehigh Bridge Company: Wm. Coyle, John McNeal, Jr., Harry H. Haines, Augustus Sausser and George F. Coffin.

The Chemical Analysis of Portland Cement; Its Possibilities and Its Limitations.

A paper read before the American Section of the International Association for Testing Materials by Richard K. Meads.

The value of chemical analysis of Portland cement is becoming more and more appreciated each year. This is due to the fact that the chemical nature of cement is being better understood. Certain compounds are recognized as possessed of certain good or bad influences. In the days when cement mixture was made upon the result of the trial kiln it was natural that little faith should be put in chemical analysis, while now that well equipped chemical laboratories are as much a part of the Portland cement plant as the kilns or the grinding machinery, more importance is being awarded to chemical analysis. It is still a very common error to suppose that because chemical analysis is not an absolute guide to the fitness of cement that it is no guide at all. It is true that the results are in themselves no certain indication of the quality of cement, yet coupled with the usual physical tests they are invaluable, not only as a check upon the physical report, but also as a line on how we may expect the cement to behave on use.

Indeed, certain engineers are now giving great prominence in their specifications to the results of chemical analysis. When important engineering work is to be done, no method should be scorned which will give us any data upon which to base our opinion on the fitness of the cement to be used. No expert upon water supply would recommend or condemn any save a decidedly good or bad water upon the result of a sanitary analysis only, yet no such expert would pass an opinion without having one made. Just as the sanitary expert compares his analysis with the topography of the land and studies the sources of contamination and the causes which tend to make each item high or low, so must the cement expert balance one item against another, and form his estimate on the whole, not from a single point. Of course, this does not apply to cements in which magnesia or sulphur trioxide exceeds the limits or in which the lime is markedly too high or too low. These can in most cases be condemned on this one count.

Cements are usually analyzed for the following constituents: Silica, iron, alumina, lime, magnesia, carbon dioxide, sulphur trioxide and water. The last two are ordinarily determined together and called loss on ignition. The variation in the percentage of any one of these elements is confined between narrow limits. In a table of over 100 analyses compiled by the writer, comprising some 30 or more brands of American, English and German Portland cements known to be of high quality, the limits of variation were as follows: Silica, 20.95 to 23.48; alumina, 5.51 to 9.74; ferric oxide, 2.28 to 4.95; lime, 58.93 to 65.59; magnesia, 0.90 to 3.18. To find that the composition of a cement lies within these limits does not assure us that the cement is all right, because the hydraulic properties depend also upon the thoroughness and the way in which these elements are combined. If, however, a cement mixture is incorrectly proportioned no amount of burning can make of it a first-class cement.

The silica, alumina, lime, magnesia, etc., are combined to form three classes of compounds: 1, Compounds having hydraulic properties, such as the trisilicate and di-aluminate of lime; 2, compounds modifying the setting and hardening of cement, either for good or bad, such as free lime, magnesia and calcium sulphate; 3, inert compounds, such as uncombined clay, sand, calcium carbonate, etc. Since we know of no compounds which absolutely modify the properties of cement for the good, the ideal cement would consist only of compounds in class 1, viz., it would be all tri-silicate, and di-aluminate of lime. The compounds in classes 2 and 3 should not aggregate more than 10 per cent. in good cement.

Chemical analysis will show us per se if such deleterious compounds as magnesia, calcium sulphate or sulphide are present in sufficient quantities to injure the cement. The analysis will also show if the cement is of normal composition. Even if the magnesia, etc., are under the limits, cements with abnormal proportions of the chief constituents, unless wanted for some special purposes, are to be looked upon with disfavor. Chemical analysis will also let us calculate by the use of the "hydraulic index" if the lime limit has been exceeded or if the percentage of lime is far under this. The analysis can be made to show the percentage of uncombined clay, sand, and calcium carbonate and can be made to serve as a check upon the burning, and also upon the care with which the mixing and grinding were done.

The experiments of Le Chatelier, Dr. Newberry and others have established the hydraulic properties of Portland cement to be dependent upon the presence of certain silicates, aluminates, and ferrites of lime. Newberry and Le Chatelier both give the formula $3CaO.SiO_2$ to the most important of these compounds, the tricalcium silicate. Assuming that this formula is correct it will be seen that the silica and lime in the compound are in the ratio of 1 to 2.8. The aluminate of lime has the formula $2CaO.Al_2O_3$ according to Newberry and $3CaO.Al_2O_3$ according to Le Chatelier. The first of these formulas is more probably correct, as it agrees closely with the best practice. Taking this as the formula for the aluminate of lime it will be seen that the alumina and lime bear the ratio of 1 to 1.1. From this Newberry deduced the following "hydraulic index" or ratio between the lime, the basic element and the silica and alumina, the acid ones:

Percentage Lime = Percentage Silica $\times$ 2.8 + Percentage Alumina $\times$ 1.1.

Most well-known Portland cements are made from a mixture of cement rock and limestone, or of clay and marl, the composition of which is practically that shown by Newberry's formula. That they do not agree exactly is due to the fact that the formula represents the maximum of lime which will combine with the silica and alumina.

This maximum is seldom attempted by any cement maker because of the danger of an excess of free lime in the cement. In order to get the silica, alumina and lime to combine, it is necessary to grind and mix the raw materials very thoroughly and burn until the lime is all combined. If the grinding is not fine enough, the mixing not intimate enough and the burning insufficient, some of the lime will remain free or uncombined and cause the cement to crack and expand in hardening.

If cement were simply the cement mixture with the carbon dioxide and water driven off, and the lime, silica and alumina properly combined, the analysis of many samples would show 90 to 95 per cent. of the lime called for by Newberry's formula. Unfortunately cement as it comes on the market is unavoidably adulterated by the ash of the fuel used in burning and by the 1 or 2 per cent. of calcium sulphate generally added to slow its setting. The ash, as it is almost entirely silica and alumina, tends to make the lime appear too low and the cement over-clayed. The addition of the gypsum if reported as lime and sulphur trioxide tends to make the lime too high. These two causes act against each other, but still leave a balance in favor of the acid elements, silica and alumina. Unfortunately for chemical analysis there is no good method for differentiating between the free lime and that combined to form hydraulic compounds. The pat test only fixes a limit. This limit is probably as high as 2.5 per cent. and in certain cements even higher than this. In some work done by the writer consisting in adding small increasing quantities of lime to cement, the free lime in which had been saturated by carbon dioxides, the checking began at about 2.0 per cent. and became marked at 2.5 per cent. With the introduction of a method for accurately quantitatively determining free lime chemical analysis will take first place as a method of ascertaining the value of cement.

The nearer the cement comes to having the maximum percentage of lime allowed by Newberry's formula, without showing free lime or under burning by the pat and needle tests, the stronger the cement will be. If, on the other hand, the percentage of lime is considerably below the limit, the cement contains a large percentage of inert material, i. e., uncombined clay, sand, etc., because the lime was insufficient to convert all the clay to silicate and aluminate of lime. For safety's sake cement always contains a small excess of uncombined clay or sand. This is shown by the percentage of silica found by fusion with sodium carbonate (or evaporation of the residue insoluble in hydrochloric acid with hydrofluoric acid) differing from that found by simple solution in dilute hydrochloric acid.

By a little modification we can easily make Newberry's formula show the minimum of lime which should be present in a good cement. Using approximate, conservative figures, it takes about 40 per cent. of the weight of the clinker of fuel to burn the former. About 10 per cent. of this coal is ash, 75 per cent. of the ash is silica and 25 per cent. in Al_2O_3. This would make the fuel ash add 3 per cent. silica and 1 per cent. alumina to that already in the clinker. The percentage of sulphur tri-oxide multiplied by 1.7 will give the lime added by the gypsum. Making these corrections and assuming that the maker should be able to carry in his mixture 95 per cent. of the lime called for by Newberry's formula, we have

Per Cent. Lime $>$ [(Per Cent. Silica — 3) $\times$ 2.8 + (Per Cent. Alumina — 1) $\times$ 1.1] $\times$ 0.95 + Per Cent. Sulphur trioxide $\times$ 1.7

Or Per cent. Lime $>$ (Per Cent. Silica —3) 2.7 + (Per Cent. Alumina — 1) $\times$ 1.0 + Per Cent. Sulphur tri-oxide $\times$ 1.7

No really first-class cement will fall below this minimum limit.

It will be seen that while Newberry's formula fixes the limits of the percentage of lime for a cement, the percentages of silica and alumina may vary. The properties of the compounds themselves, however, regulate the proportions of each, for the tri-silicate of lime gives the hardening powers to cement while the rate of setting is supposed to be controlled by the di-aluminate of lime. Portland cement usually contains from 7 to 10 per cent. iron oxide and alumina together. As the percentage of alumina increases in a cement other things being equal, it becomes more and more quick-setting, and, on the other hand, as the silica increases under similar conditions, its set becomes slower but it will ultimately develop greater hardness.

Iron oxide is supposed to have similar hydraulic properties to alumina. Aside from this it has a decided effect upon the color of the cement. Probably if present in the ferrous state, its action is deleterious and it also points to adulteration of the cement with blast furnace slag, or to cement burned with a strongly reducing flame, either of which show poor cement. In cements examined by the writer made by the rotary process the ferrous iron present was under 0.2 per cent.

The chemical analysis gives us a splendid insight into the care and skill with which the cement has been manufactured. For example, suppose that a cement contains a normal percentage of alumina and yet sets very rapidly. Then the cement is under-burned or the raw materials were poorly mixed. These latter causes tend to make cement quick setting. On the other hand, if the cement sets very slowly and does not contain an excess of calcium sulphate, then it may be diagnosed as over-burned. Again, if the cement is proportioned correctly, according to the formula given, and yet shows free lime when tested by the pat test, the raw materials were probably poorly mixed, not ground fine enough, or the burning was insufficient.

Manufacturers are more prone to sin on the side of under-burning than of over-burning, since over-burned clinker is a very hard substance to grind while under-burned clinker is much easier. Probably the separate determination of carbon dioxide and of water in cement would also aid very materially in getting a line on the burning, as well as explaining many of the freaks of setting so often met. Fresh under-burned cement will show high loss on ignition. This loss is entirely carbon dioxide; on the other hand, cement which has stood some time and has a high loss on ignition due to saturated free lime usually shows as much water as carbon dioxide.

Another test which gives us a good indication of the burning is the difference between the silica by solution in hydrochloric acid and that by fusion with sodium carbonate, since the tri-silicate and di-aluminate of lime are entirely soluble in hydrochloric acid. A simpler way of applying the test is merely to note the residue left on evaporation of the insoluble matter with hydrochloric acid. This residue in a well-made cement should not exceed 0.3 per cent.

In valuing cement the writer suggests that the chemical analysis conform to the following limits: Percentage of silica, 20 to 23; Alumina, 6 to 11. Percentage of lime less than 2.8 times the percentage of silica plus 1.1 times the percentage of alumina. Percentage of lime greater than 2.7 times (the percentage of silica — 3) plus (the percentage of alumina — 1) minus 1.7 times the percentage of sulphur tri-oxide. Percentage of magnesia less than 3½ or even 3. Percentage of sulphur tri-oxide less than 2 or even 1½.

It should be borne in mind, however, that a change in our knowledge of how to make cement may narrow at any time these limits, more especially with regard to the minimum of lime and also of the silica, which is made unnecessarily high by contamination with the fuel ash.

The Power Equipment of a Buffalo Grain Elevator.

A remarkable grain elevator was recently put into service by the Iron Elevator & Transfer Company, of Buffalo, N. Y. It is built entirely of concrete and steel, and is situated on the Lake Shore & Michigan Southern Railroad. All grain passing East over this road is weighed and transferred from Western into Eastern cars at this elevator, which has an actual working capacity of 60 carloads in and out in a 10-hour day. In addition to the regular work of transferring grain in transit, the elevator is equipped for cleaning and separating the mixed grains and, for this purpose, has a storage capacity of 650,000 bushels, divided into 90 steel bins, with a capacity of from 1,000 to 12,000 bushels each. The bins are of rolled steel plates, cylindrical in shape; they are 65 feet deep, and the largest ones are 15 feet in diameter. The foundation is of concrete and is built at a sufficient altitude above the ground to form a working story or basement 10 feet high under the bins.

The grain is handled throughout the building by means of endless rubber belt conveyors and elevating legs which are driven entirely by induction motors located at various points in the structure. The aggregate power provided amounts to 280 horse-power, which is divided among five Westinghouse induction motors, varying in size from 30 to 75 horse-power each. The power is transmitted from the motors to the machinery by rope drives in every case. The cleaning and clipping machinery, located in the second story of the track shed, is all driven by motors; one 50 horse-power motor is connected by a rope drive direct to a large clipper. A 30 horse-power motor is also used to drive a powerful car-pulling machine in the basement.

Electric power is received from the Niagara Falls power circuits in the form of three-phase, alternating current at 2,200 volts. This voltage is transformed to 400 volts for distribution in the elevator. All motors are controlled from a fire-proof electrical room in the basement of the elevator by means of a switchboard from which the wires pass through iron conduits to the motors. In this manner all sparks attendant upon the starting and stopping of the motors are confined to this room and the danger of dust explosions and fires originating from the electrical apparatus is reduced to a minimum.

Compressed air is distributed to all points of the elevator. This air, at a pressure of 100 pounds per square inch, is available throughout the building, and is used for blowing dust out of the motors, for sweeping floors and beams and for syphoning any water that may collect in the drain pits under the elevator. A blacksmith's forge is also supplied with air from this system.

In addition to the iron elevator just described this company owns an older wooden transfer elevator and a very large feed grinding establishment, known as the Diamond Mills, situated near the wooden elevator. The former is a railroad grain elevator of the old fashioned wooden crib type, which has been operated heretofore by steam with great economy, owing to the fact that dust and clippings from the grain were burned as fuel. The Diamond Mills, also, received power for their operation from the plant of the wooden elevator. In spite of this economy, however, both establishments will hereafter be operated by Westinghouse induction motors, receiving current from Niagara Falls, the change being made as a result of the marked saving in cost of operation of the new iron elevator, as compared with that of the old wooden house. The power equipment for these two plants is now being installed and will aggregate about 500 horse-power, comprising the following apparatus: three 75-kilowatt oil-insulated transformers, provided with special tap from which a suitable starting voltage for the motors can be obtained; a 100-horse-power three-phase induction motor and three 75-horse-power motors, three of 50 horse-power and one of 30 horse-power.

Grain Spouts and Motor-Driven Conveyor Belt in Basement.

All the electrical apparatus above mentioned has been furnished by the Westinghouse Electric & Manufacturing Co. Credit for the engineering and construction work is due to the Macdonald Engineering Company, of Chicago.

Tar Macadam.

Extracts from a paper presented to the Midland Municipal Officers' Association by Mr. George H. Owen, Road Surveyor of Nottingham.

Tar macadam is composed of stones cemented together with a mixture of tar and pitch, or tar, pitch and creosote oil. The stone must be perfectly dry, and if at all possible mixed when it is warm, as less tar will be required and it will be more easy to manipulate. The drying process differs in the various towns, but, in my opinion, the kiln or drying floor as used in Nottingham is by far the best. It is composed of iron plates built upon brickwork about 2 feet above ground level, with two fires at each end and the chimney in the middle. The cast-iron plates, about 4 feet by 3 feet and 1 inch thick, are supported upon 4½-inch intermediate walls, which are pigeon-holed to allow the heat from the fires to circulate freely under the floor in its passage to the chimney. The fireplaces, which are carried under about 3 feet, must have a fire-brick roof between them and the drying floor, to prevent the iron from getting red hot and warping. This roof also distributes the heat more evenly. Two large coppers for boiling the tar are placed at one end, capable of holding about 80 gallons, the fire flues of which also pass under the iron floor. The stone is laid on the kiln from 6 inches to 1 foot thick, according to the amount of drying required, and if it is very wet it will be found necessary to turn it over once or twice. While it is necessary to have the stone dry and warm, care should be taken that it is not too hot or it will burn all the nature out of the tar. As regards the stone to be used, it will be found that the tar will adhere better to a porous stone, such as limestone or slag, than it will to granite or whinstone. At Nottingham slag is the chief, and I may say the only, material used, and the sizes are 2¼ inches for the bottom and ¾ inch for the top layer.

The tar mixture to be applied varies considerably, as the quality of the tar differs so much. Thin tar either requires more boiling than thick tar, or it should be stiffened by the addition of some pitch. Tar that has been distilled must not come to a boil, or it will become unworkable and will not incorporate freely with the stone. I do not recommend the use of pitch unless the macadam is to be used at once, for if the tar is boiled sufficiently it will be found to equal the tar and pitch mixture in cementing properties and be far superior in elasticity and covering power. From observations I have found that tar boiled properly has much more life in it and will not perish nearly so quickly as when pitch and creosote oil are added to it. An average time for boiling will be one and a half to two hours, and it should be stirred frequently to prevent it from boiling over or burning. To test the quality of the tar it is a good plan to have a small tin of it boiled over a Bunsen burner and mix some at intervals with some chippings. From these samples one can then determine what time will be required for boiling to bring it to its right consistency. When a workman has had a little experience he can generally tell when the tar is ready by getting a little between his forefinger and thumb. If it rubs off the finger easily it has not been boiled long enough.

The best method of mixing is to have a large bucket, say to hold 10 or 12 gallons of tar. Place two barrows of stone, about 6 inches thick, as a "bottom," on the top of which two men shovel the stone off the kiln while another keeps pouring the tar over it by means of a ladle until the bucket is empty. Then, if the turning be commenced and continued from the bottom of the heap, the stone itself in falling and working will be found to assist greatly in the mixing. It will facilitate in the work to a great extent if a good smooth floor is provided for mixing on, and the workmen should have instructions to keep this floor clean. Two men can mix 10 tons per day of 10 hours. From 8 to 9 gallons of tar (if pitch is added reckon about 10 pounds to a gallon) will be required to coat 1 ton of stone when it is warm, but this amount will vary according to the quality of the tar and the nature of the stone. Granite does not require as much tar as slag, and either of these materials with a quantity of chippings and dust will take more than the clean stone. The treated stone should then lie in the heap about three weeks or a month, but if it is required for immediate use a little pitch, say 2 to 4 pounds per gallon of tar, should be added. While it is necessary to have the stone free from dirt, a quantity of dust and chippings, sufficient to fill the interstices, will augment the binding and ensure a compact mass.

The material when ready for use is laid upon a good, hard, dry rubble foundation. First a layer of 2¼-inch material which, when rolled, is about 4 inches deep, and then a layer of ¾-inch to a thickness of 1 inch. When this has been rolled for some time slag dust or fine gravel is scattered over it and the rolling continued until the whole is consolidated. All wet and moisture should as far as is practicable be kept away from the foundation and the tarred stone, and the work should therefore be carried out in dry weather. A very bad practice is to water the stone before the roller passes over it, to stop the tar from adhering to the wheels. This undoubtedly reduces the life and elasticity and also the affinity of the material. If the roller is kept going over the raw tarmacadam during the coolest hours of the day, say until 10.30 a. m. and from 3 p. m., it will be found that very little will adhere to the wheels, and in the meantime rolling the parts which have already been dusted will be found both practicable and beneficial.

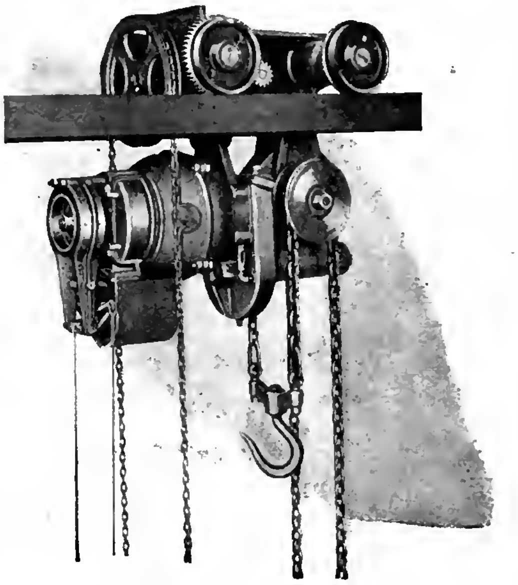
It will be found that tar macadam, if properly mixed and laid, does not begin to wear as soon as the traffic commences to pass over it. Owing to its elastic nature some time elapses before it is completely consolidated and it acts like a cushion to the foundation for a couple of years. When it does begin to wear, and little ruts and hollows make their appearance, they should be "picked out," swept clean, painted with a little hot tar, and a layer of tarred chippings put in and rolled. When a road is very much worn it is best to thoroughly pick the surface to a depth of 3 inches, clean all dirt and all material away, paint or sprinkle lightly with hot tar and resurface in the same manner as for new work. The old material if screened free from dirt can be treated with a little hot tar without the addition of pitch and used again. A very good way of preserving tar macadam is to thoroughly clean the surface, paint with hot tar and sprinkle with slag dust on fine gravel. This is called "floating," and is chiefly adopted in streets where there is very little traffic.

The cost of tar macadam in Nottingham is, roughly, about 40 cents per square yard for materials and labor only. Judging from experience, from 50 to 75 per cent. less labor is required in cleaning it than in cleaning ordinary macadam. Its greater first cost in comparison with ordinary macadam is more than offset by its greater durability.

A New Electric Hoist.

Various attempts have been made to design an electric hoist capable of handling heavier loads than come within the range of hand hoists, and not requiring the heavy and expensive supporting structures necessary to carry the large amount of dead weight of ordinary traveling cranes. The hoist, shown in the accompanying illustration, designed specially to fulfill these requirements, is protected by patents owned by the Sprague Electric Company. It is intended to transfer light work rapidly around shipyards, factories, etc., and, when supplied with trolley carriage, geared hand cross travel and a bridge travel motor, to take the place of small traveling cranes. It consists of few parts, all of which are interchangeable. It is easily adaptable to all types of runways and bridges, and the sizes range in maximum capacities from 1,500 to 10,000 pounds. The smaller sizes can be equipped with a trolley arranged to run on a single rail, or I-beam, and, if so arranged, will take curves of a reasonably small radius.

All the different movements necessary for a traveling crane, hoisting, lowering, cross-travel and bridge-travel, are controlled by simply pulling the chains and cords connected to the mechanism, which can be done by the ordinary workman to be found in the place where the



The Sprague Hoist.

hoist may be used. No special crane operator or cage is necessary. The motor and hoisting mechanism can be hung from a strap if only a hoist and lowering motion is desired, or they can be attached to a trolley carriage arranged for cross-travel, either by pushing the load or by a geared hand traverse motion. A bridge-travel is also provided, the controller for which is mounted on the end of the trolley carriage as shown in cut. This controller is operated by cords, the handles of which are located near the work. The bridge-travel motor itself is mounted in some convenient position on the crane; the bridge-travel motion is reversible, and in practice it is possible to obtain a very short movement in either direction.

The motors furnished with this equipment are Lundell round type motors entirely enclosed and the hoist can be operated out of doors without being affected by the weather. The resistance plates for the bridge-travel controller are of the enclosed type, and have a very large overload capacity. The company manufactures the complete hoist as shown, consisting of hoist wheels and chain, worm and spur gear, gear cases, hoisting motor and attached cylindrical switch, trolley carriage, geared hand operated cross-travel of trolley carriage, and motor and controller for bridge-travel of crane. The hoist and motor can also be furnished complete without trolley carriage or with trolley carriage and geared hand cross-travel, but without bridge-travel motor and controller. The company does not manufacture cranes, but will equip them with this apparatus including wiring. A complete description of the hoist will be given in Bulletin No. 2,098 to be issued from the New York office of the company.

The Relative Rights of Power Plant Owners and Cities to River Water.

An opinion by the Ohio Supreme Court in City of Canton v. Shock et al., 63 N. E. Rep. 600.

The city of Canton is a municipal corporation, and is situated between the east and west forks of Nimishiller Creek; the forks meeting at or near the south line of the city, and thus forming that creek. The entire natural drainage of the city is toward and into these two forks of the creek, which is a natural water course. The city has established its system of water-works on the west branch of the creek, on a lot of land adjoining said branch; and it takes its water supply from said creek, and from certain wells near the same, and from Myers' Lake, near by. The city uses so much of the water supply thus passing through its water-works as it needs for its use as a city, and supplies its inhabitants with water for domestic, commercial, and manufacturing purposes, at a price fixed by the city, so as to produce an income about sufficient to pay the expenses of said water-works.

The defendants in error own a water-power grist mill, located on the creek, a short distance downstream, south of the city, and have used the water of the creek for many years—over 50—as power to run their mill, and until about the year 1887 there was sufficient water to supply both the city and the mill; but as the city grew, and extended its water-works, it used larger quantities of water, and thereby the supply to the mill became reduced to such an extent that in dry seasons of the year there was not sufficient water to run the mill all the time, and it became necessary to shut down at nights. Thereupon, in the year 1898, the defendants in error (plaintiffs below) commenced an action against the city in the court of common pleas, seeking to recover damages from the city for thus using the water, and thereby diminishing the supply to the mill. The city claimed to be a riparian owner, and entitled to make such use of the water of the stream as it had made, and that the plaintiffs below had no greater right to the use of the water to run their mill than the city and its inhabitants had to use the waters of the creek above the mill for domestic, commercial and manufacturing purposes.

Upon the trial of the case these questions were put in issue by the pleadings and evidence. Thereupon the court charged the jury as follows: "On the question of the right of the city to take this water for the purposes named, the defendant claims that substantially all the water diverted by it from the creek in question, and which was not returned to said creek, was used for the purpose of supplying the inhabitants of the city, and a small portion of territory adjoining thereto, with water for domestic, sanitary, agricultural and manufacturing purposes; that said stream does now and for many years has passed in and through the corporate limits of said city; that it owns the premises upon which its pumping station is situated, and has lines of pipe proceeding from said creek and pumping station, and passing through the city, to supply said persons; and that it is, in a sense, a riparian owner located on said stream, and it claims that the inhabitants of said city so supplied by it have the rights of riparian owners in said stream—that is to say, the right to use the same for domestic, agricultural, sanitary, and manufacturing purposes; and I am requested by the defendant's counsel to say to you, as matter of law, that if these facts are true, and if the water so drawn from said stream, and not returned to it so as to be effective for plaintiffs' water power, was substantially all consumed by the citizens of said city, and territory adjoining thereto, for the purposes and uses aforesaid, and if their uses were reasonable in manner and extent, then the city would not be liable to the plaintiffs, although such use might so diminish the volume of said stream that at certain times of the year it would cause a substantial diminution of plaintiffs' water power. I say I am asked by defendant's counsel to so instruct you, but I cannot so instruct you, as matter of law. On the contrary, I say to you, as a matter of law, that the undiminished flow of a natural private stream, such as the one in question is conceded to be, is the right of every riparian owner, yet this right is limited to this extent: that each riparian owner may, without subjecting himself to liability to another lower riparian owner, use of the stream whatever is needed for his own domestic purposes and the watering of stock. The defendant, the city, cannot be considered a riparian owner, within the scope of this exception."

The city saved exception to this part of the charge, and to the charge as a whole. A verdict was returned in favor of plaintiffs below, motion for new trial overruled, judgment entered on the verdict against the city, and a bill of exception allowed, signed, and made part of the record. The circuit court affirmed the judgment, and thereupon the city filed its petition in error here, seeking to reverse the judgments below.

As this is an action against the city for damages, no question as to eminent domain, or appropriation of private property for public uses, is involved in the issue; the controlling issue being as to whether the city, as a municipal corporation, is a riparian proprietor having the right to use the waters of the creek for its own purposes, and to supply them to its inhabitants for the ordinary purposes of life, and as to whether the right to use water from a stream by one riparian proprietor for manufacturing purposes, such as running a gristmill, is inferior or equal to the right to use the water from the same stream by an upper proprietor for domestic purposes.

It is urged by counsel for defendant in error that a municipality situated on a natural water course is not, in its corporate capacity, a riparian proprietor, and that only those inhabitants whose lots or lands border on the stream are such proprietors; and some cases are cited which seem to take that view of the law. Other cases are decided upon the theory that such municipality is itself, in its corporate capacity, a riparian proprietor, and entitled as such, to riparian rights in the stream upon which it is situated. Water Co. v. Carnes, 27 Atl. 609; Mayor, etc., of City of Philadelphia v. Spring Garden Com'rs, 7 Pa. 348; City of Philadelphia v. Collins, 68 Pa. 106; Jones, Easem. Sec. 747, and cases cited in a note to the section. In this State the question remains undecided by this court, and therefore is an open one, and we are at liberty to follow such rule of decision as is supported by sound reason and the weight of authority.

It was held by this court at this term in City of Mansfield v. Balliett, 63 N. E. 86, that a city situate on a stream is liable in its corporate capacity to a lower proprietor for polluting the water of such stream by running the sewage of such city and its inhabitants into such stream. This case holds the city, in its corporate capacity, and as an upper proprietor, liable to a lower proprietor for polluting the water of the stream; and if the city is liable not only for its own acts, but also for the acts of its inhabitants, in flowing sewage into the stream, it must be upon the principle that, as upper riparian proprietor, it has violated its duty toward a lower riparian proprietor on the same stream, and that therefore the city, in its corporate capacity, is a riparian proprietor on the stream, and must bear the burdens of such position. While the inhabitants own their lots individually, the city owns the streets, the fire department, and all other public property and public works, and, in its corporate capacity, provides for the convenience and welfare of its inhabitants as to streets, fire protection, lighting and supplying water; and in such and other like matters the city overshadows the individuals, and stands in its corporate capacity as a single proprietor extending throughout its entire limits, and entitled, as such, to all the rights, and subject to all the liabilities, of a riparian proprietor on the stream upon which it is situated. Sound reason, the weight of authority, and the present advanced state of municipal government, rights, and liabilities, require that a municipality should be held and regarded, in its entirety, as an individual entity, having in its corporate capacity the rights, and subject to the liabilities, of a riparian proprietor; and we so hold in this case.

The bringing of the action against the city for damages is of itself an implied admission that the city, in its corporate capacity, is an upper proprietor, liable for the wrongful diversion or use of the water of the stream upon which it is situated. Being charged with the liability of such upper proprietor, as conceded by bringing the action, and as was rightly held in the City of Mansfield Case, it must also be accorded the rights and benefits of such proprietor. As such proprietor, the city uses the water of the stream, through its water-works, in extinguishing fires, sprinkling streets, and other public purposes, and supplies water to its inhabitants for domestic use and manufacturing purposes. Being an upper riparian proprietor, it follows, as a matter of law, that it has the right to use out of the stream all the water it needs for its own purposes, returning to the stream all that is not consumed in such use; not, however, transporting the water, as was done in Railroad Co. v. Miller, 3 Atl. 780, nor diverting the water, as was done in Wheatley v. Chrisman, 24 Pa. 298. The right of an upper proprietor to use the water of a stream for manufacturing purposes is at least equal to the right of a lower proprietor on the same stream to use the water for a like purpose; and so long as the upper proprietor uses the water reasonably, and returns all the water not consumed in the use back into the stream, the legal rights of the lower proprietor are not invaded. There being no right of property in the water of a natural flowing stream—the only right being to the use of the water as it flows by the lands adjoining the stream—it follows that, as the water comes first to the upper proprietor, he may use it reasonably for power purposes, returning to the stream all that is not consumed in the use, and that the right of the lower proprietor attaches only to the use of the water that comes to his premises after passing, and so serving the purposes of the upper proprietor.

As the right of the city to supply water to manufactories within its bounds for power purposes is only equal to the right of a lower proprietor to use water for the same purpose, the question arises in this case as to the rights of the parties to use the water of the stream for such purposes. The question is a difficult one, both in theory and application, as the different sizes of streams and different circumstances have caused courts to make different holdings, but the combined result of the cases seems to be: That where there is not sufficient water in a stream to supply fully the needs of all the proprietors on the stream for power purposes, no one has the right to use all the water, and thereby deprive those below him from the use of any; nor can those below rightly insist that those above shall use no water for power, and thereby save it all for those below. Each should use the water reasonably, and so as to do as little injury to the others as circumstances will permit. As a loss must fall upon one or the other of such proprietors, neither should be compelled to bear the whole loss, but the water should be so divided and used that each one may bear his reasonable proportion of the loss. And that, in case of difference between upper and lower proprietors, in such cases the question should be left to the sound judgment of a jury, under proper instructions, to say whether the party complained against has used for power purposes, under all the circumstances, more than his just proportion of the water of the stream. Evans v. Merriweather, 3 Scam. 492. This being so, the city of Canton, in supplying water to its inhabitants for power purposes, had the right to use the water of the stream to a reasonable extent only, and so as to do as little injury as might be, under all the circumstances, to the lower proprietor; each party bearing an equitable share of the loss caused by the shortage of water. Dry seasons are not caused by either party, but are the act of God, and each party must bear the losses resulting to him therefrom.

From the earliest dawn of history to the present time, the primary use of water has been for domestic purposes, and its secondary use for the purposes of power. People on the upper stream have the right to quench their thirst, and the thirst of their flocks and herds, even though by so doing the wheels of every mill on the lower stream should stand still. Railroad Co. v. Miller, 3 Atl. 780. And the same right in the use of water as to quenching thirst extends to all uses for domestic purposes, and the right of a lower proprietor to the use of the waters of a stream for power purposes is subject to the superior right of all upper proprietors for domestic purposes, and must yield thereto. All water powers on a stream are established subject to the superior right of all upper proprietors to use water out of the stream for domestic purposes, and if the upper proprietors have grown so large or become so numerous as to consume most or all of the water, the lower proprietors have no cause of complaint, because it is only what they should have reasonably expected in the growth and development of the country, and subject to which contingency they established their water powers.

In addition to taking water from the stream for its own use, and supplying the same to its inhabitants for domestic and manufacturing purposes, the amended petition avers that the city supplied water to its inhabitants for commercial purposes. If this means only that the city received pay for the water so supplied, and thereby made the water an article of commerce, the averment is of no force. The city having the right to supply water to its inhabitants for domestic and manufacturing purposes, it can make no difference in that right that the supply is for pay, rather than for nothing. The injury, if any, to the lower proprietor, arises from the taking of the water, and not from the pay received therefor.

It is also averred in the amended petition that the city supplies water to people outside of the city for domestic, commercial, and manufacturing purposes. If such supply to outsiders, or to be transported away from the city for commercial purposes, is sufficient in quantity to materially injure defendants in error, taking into consideration the size of the stream and water supply, the city, to that extent, is exceeding its right as a riparian proprietor. The general rule is well stated by Paxson, J., in Railroad Co. v. Miller, 3 Atl. 780, 781, as follows: "The principle established by a long line of decisions is that the upper riparian owner has the right to the use of the stream on his land for any legal purpose, provided he returns it to its channel uncorrupted and without any essential diminution; that in all such cases the size and capacity of the stream is to be considered, and that any interruption of or interference with the rights of the lower riparian owner is an injury for which an action will lie, unless too trifling for the law to notice." The obligation to return the water to the stream without "any essential diminution" means that the water not consumed in the use or "legal purpose" must be returned to the stream, or an opportunity given for it to flow back into the stream by the ordinary channels. It cannot be lawfully diverted or transported, so as to prevent it from flowing back into the stream.

The city having no right to materially diminish the flow of the water in the stream to the injury of defendants in error by supplying water to outsiders, or for commercial purposes to be transported to other parts, or to supply to its inhabitants for power purposes an unreasonable quantity, as above pointed out, it follows that if the city has materially diminished the flow of the water in the stream by so supplying water to outsiders or for transportation, or unreasonably for purposes of power, it is liable to respond in damages to the party injured thereby; but for the water consumed by the city for its own purposes, or so supplied to its inhabitants for domestic use, even though it received pay therefor, it is not liable. The water taken by the city from the stream for its own use, and so supplied to its inhabitants, is taken by virtue of its rights as a riparian proprietor, and not by virtue of the right of eminent domain, and therefore no compensation need be made therefor.

The general rule that a lower proprietor is entitled to the natural flow of a stream undiminished in quantity, subject to the lawful use of the water by upper proprietors, has been referred to with approval by this court in several cases. Iron Co. v. Tucker, 26 N. E. 630; City of Mansfield v. Balliett, 63 N. E. 86. In the City of Mansfield case there was no question involved as to the volume or quantity of water; the only question being as to the liability of the city for polluting the waters of the stream, and the right of the lower proprietor to recover damages for such pollution. The case of Iron Co. v. Tucker, supra, was also by a lower proprietor against an upper one for damages for polluting the waters of a stream. The question as to the pollution of the waters of a stream in this State seems to be fairly well settled by these two Ohio cases, but they do not determine the relative rights of upper and lower riparian proprietors as to the use of the waters of a stream, as was so strongly urged by counsel for defendants in error.

The court of common pleas erred in its charge to the jury as to the city being an upper riparian proprietor, and as to its right to use water out of the stream for its own purposes, and as to its right to supply water from the stream to its inhabitants for domestic and manufacturing purposes. The real and only question upon which a liability could be founded, viz., whether the flow of the water in the stream was materially diminished, to the injury of the lower proprietors, by the supplying of water by the city to people outside of its limits, or to be transported away from the city for commercial purposes, or by an unreasonable supply of water for power purposes, seems to have been overlooked, and no charge requested or given on that subject.

The circuit court erred in affirming the judgment of the common pleas. Both judgments will be reversed, and the cause remanded for further proceedings. Judgments reversed.

The Reconstruction of the Redheugh Bridge, England.

The recent reconstruction of the Redheugh highway bridge at Newcastle-on-Tyne, England, was an undertaking of considerable difficulty owing to the necessity of interfering as little as possible with the heavy traffic while removing and erecting spans of a character that made rapid work impracticable. The old highway bridge, completed in 1871, had two river spans of about 252 feet each, two side spans of 167 and 168 feet, and short-span masonry arch approaches making a total length of 1,187 feet. The width over all was 41 feet, including a 20-foot roadway and two 7-foot sidewalks. It had a clearance of 86½ feet above high water and the river spans were supported on three iron towers each with four vertical columns on separate masonry piers. The towers were extended about 40 feet above the top chords of the main spans and carried diagonal longitudinal tension members attached to the bottom chords at points one-third of the way between the piers so as to form auxiliary back stays of suspension guys. The old trusses were riveted lattice girders with cast iron gas mains for inclined top chords and had water mains laid inside the trough-shaped bottom chords.

The piers of the approach arches were used for the new plate girder approach spans and all the rest of the old structure was entirely removed and replaced by the new one, which had spans of the same length and greater width on the same center line and at the same grade. The new piers each consisted of four 8-foot steel cylinders filled with concrete and sunk 50 feet or more below the river bed by the pneumatic caisson process. The cylinders in each pier were 12 feet apart longitudinally and 55 feet apart transversely, on centers. They were built in 4½-foot courses with 6-inch inside circular cover splices and contain permanent 3-foot air shafts between which and the outer shell concrete filling was placed as the pier sunk. After sinking the shafts were also filled with concrete. The contractors were not allowed to reduce the pressure in the working chamber to sink the cylinders, or to move the air lock but once, and a timber grillage was kept inside the working chamber to prevent any inflow of mud. The concrete was not dumped in the cylinders from a height of more than 8 feet and after being placed it was shovelled and trodden by men with rubber boots.

The tops of the cylinders are 6 feet above high water level and are connected by single longitudinal plate girders 3 feet deep and 4 feet long with their center points about at the high-water level and riveted through vertical and horizontal flange angles to the opposite faces of the pairs of cylinders. Each transverse pair of cylinders is well braced.

Each pair of cylinders supports one bent of the tower which is made with a pair of 60-foot columns battered about 1:7 in a vertical transverse plane. Each column is made in three sections and has a cruciform cross-section made with a 36-inch and a 39-inch web connected at their intersection with four 3x3½-inch angles and having two 6x4-inch angles in each flange. The columns are spliced with planed butt ends and flange and web cover plates and their flanges are tied every 6 feet by 3x2½-inch bent angles riveted around the column like a ring. Each bent is divided into three vertical panels by the transverse girders at the top and by a bottom and two intermediate horizontal transverse struts. The width of the strut equals that of the column and its ends form jaws which engage and are riveted to the column flanges. Each panel is X-braced by two pairs of 9-inch plate diagonals, spliced at both ends with double cover plates to the main connection plates. At one end these plates are riveted to the column flanges and at the other end, where the diagonals intersect, they are riveted to a vertical compression member which connects the center points of the transverse horizontal struts.

The tops of the two bents in each tower are connected by four horizontal longitudinal plate girders 12 feet long and 6 feet 9½ inches deep, one girder being riveted across the flanges of each side of each column. Each pair of girders is connected by transverse diaphragms and top flange cover plates. Below the longitudinal girders the bents are connected by 3x3½-inch angle lattice bars, riveted in place as the columns were erected, section by section. Across the top flanges of the longitudinal girders in each tower are seated four transverse plate girders, 6 feet 9½ inches deep and 48 feet long, which overhang 8 feet at each end and have their top flanges flush with the tops of the columns. Bearing plates ½ inch thick are riveted across the tops of the columns and transverse girders to make a solid platform for the pedestals for the trusses of the main spans.

The pedestals are of cast iron, made in two pieces with half holes to fit a 12-inch pin with collars engaging the sides of the pedestals and long ends projecting beyond them on both sides, for use in erection. Each part of the pedestal has one vertical web parallel to the pin and five at right angles to it, the latter staggered in the upper and lower pieces, and the former in the plane through the axis of the pin. The fixed end pedestal is seated directly on a solid forged steel bed plate 42 inches square and 6 inches thick. A nest of segmental 10-inch rollers 5¾ inches wide is interposed between the shorter pedestal and the bed plate at the expansion end of the span.

The main span trusses are of the Pratt type with riveted connections and main panels 16 feet long with horizontal and vertical struts intersecting at the center and a sub-diagonal strut from the center to the bottom chord panel point. The top chords have a trough-shaped cross-section made up of 4x4-inch flange angles, 20x20x$^{12}/_{20}$-inch web plates and 34x1-inch top cover plates. The bottom chords have similar cross-sections with additional inside flange angles, inside cover plates and transverse vertical diaphragm plates. The compression web members are built up of angles and plates latticed, and the main tension diagonals are plates, stiffened at the lower ends with T-bars. The counters have forged steel couplings with screw adjustments through which holes were drilled and pins driven and riveted to lock them after erection.

Plate girder floorbeams 4 feet apart are suspended by vertical angle irons riveted to both webs of the lower chords and carry shallow I-beam stringers 4 feet apart which are supported on shelf angles and are covered with a buckle plate solid floor, paved. The floorbeams are 53 feet long and have tapered cantilever ends extending about 13 feet beyond the trusses and 6½ feet beyond the sidewalk hand rails to carry the gas and water mains. There is one panel of sway bracing between the tops of each transverse pair of vertical posts, and there are light lateral diagonals in the plane of the top chords between the top struts of the sway frames.

Erection was commenced with the reconstruction of the approaches which were built in successive longitudinal halves. Centering was placed under all the masonry arches and the western half of each was taken down simultaneously so as not to impose any unequal thrusts on the piers. The piers were then built up to the required height on the west side of the axis of the bridge and the plate girder viaduct built over them and the roadway constructed. The traffic which had previously been maintained over the old arches in the eastern side of the bridge was then diverted to the new roadway and the eastern half of the approaches built in the same manner. While the approaches were being reconstructed the new piers were built, their cylinders and towers clearing the old ones and allowing most of the tower bracing to be connected up outside the old towers.

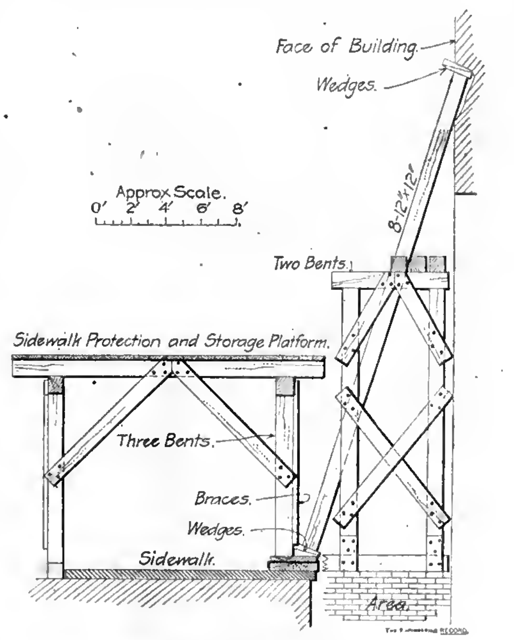
The new main spans were erected with their center lines parallel to the axis of the bridge and 4½ feet away from it so that the new trusses cleared the old ones and could be assembled without interrupting the traffic which was maintained on the old roadway. The adjacent ends of the trusses in the four main spans were built out from the three river piers as connected double balanced cantilevers without any support from the old structure. In erection the ends of the trusses were pivoted on their pedestal pins and the pedestals were blocked up above the required heights.

The gusset plates at the hip joints were extended beyond the inclined end posts and were pin-connected to horizontal tension bars which at the opposite ends were pin-connected to short links over the center of the pier and thus formed ties between the adjacent ends of the trusses in the same plane. The ends of the center link were connected by two pairs of vertical bars with the projecting ends of the pedestal pins of both spans. The vertical bars were made in three sections each, the middle section having 2¾-inch screw ends with nuts bearing on a horizontal yoke, permitted an adjustment of nearly 3 feet. By means of this toggle the ends of the semi-spans were elevated or depressed to meet at the center panel for final connection. During erection the short spans were counterweighted to make their moments around the pier centers equal those of the long spans. After the trusses were erected and the toggles were removed the ends of the spans were lifted by hydraulic jacks placed under the projecting end pins, the packing was removed and they were lowered to their final level and the four spans, weighing complete about 1,600 tons, were moved 4½ feet transversely to final position.

The reconstruction of the bridge occupied four years and was executed by Sir William Arrol & Company, Glasgow, contractors, Mr. George Huntley resident engineer. Messrs. Sandeman & Moncrieff, Newcastle, were the designing engineers. The bridge has been illustrated in "The Engineer," "Engineering" and other English technical journals from which the foregoing description has been condensed.

Replacing a Stone Front.

The six-story and high-basement building at No. 38 Wall Street, New York, has brick walls with carved stone lintels extending across the 21½-foot front between the lower stories. The entrance was originally at one side but the building is being remodeled and the entrance changed to the center, the brick and stone front replaced up to the third story, and two new cast-iron columns inserted on the sides of the new entrance. This involves temporarily supporting the front above the second story while the old facing and lintels are removed and the new are put in place. The upper part of the wall and the floor loads which it carries are supported by a fourth-story stone arch having a span of the full width of the building, and the upper part of the brickwork below the arch is carried by a plate girder of the full length of the wall and supported like the arch on the piers at the corners of the building. These members leave only a comparatively small weight to be provided for during repairs, and it was at first intended to carry it by horizontal needles put through the wall under the third floor. The tenant would not consent to this and the wall had to be supported entirely from the outside, which was done by a system of inclined shores arranged as shown in the sketch.



SHORES AND PLATFORMS.

A row of eight 12x12-inch timbers about 30 feet long are arranged in pairs, one on each side of each window, and seated on a double tier of distributing planks on top of the thick sidewalk flagstones close to the area wall. The first tier of planks are parallel to the face of the building and are anchored by three transverse flat steel straps with their ends bent down at right angles and engaging the edge of the coping of the area wall. The shores have both ends cut off square and take bearing on pairs of wooden wedges driven against the sill pieces and against the brickwork at the third floor level at the top of the shores, where cloth or some other soft packing is interposed between them and the brickwork to prevent cracking the latter. The shores are set so close together that they cover over one-third of the wall area.

At each end of the row is a two-post transverse bent, having vertical posts scabbed to horizontal sills and caps. The former rest on the sidewalk beyond the ends of the area and the latter support three long horizontal timbers between the wall and the shores. These timbers form a platform to receive the new 21½-foot by 2-foot 10-inch by 1-foot 2-inch stone lintel, which is estimated to weigh about four tons and will be run in under the shores close to the building at street level and then hoisted horizontally by tackles suspended from breast derricks set on an outside scaffold. This is the ordinary sidewalk protecting platform and has a solid deck of longitudinal planks supported about 12 feet above the curb on three transverse bents with transverse and longitudinal kneebraces at their tops. All the timber except diagonal braces is 12 x 12-inch and the structure is much heavier than is considered necessary to carry the load. No jack screws are used and great care is taken with the arrangement and driving of the wedges, the latter are arranged with their upper surface horizontal at the tops of the shores and their lower surfaces horizontal at the bottoms of the shores, and have so small an angle that there is no danger of their slipping or allowing the shores to kick out.

Mr. Ernest Flagg is the architect of the building and Mr. Edmund D. Broderick is the contractor.

The Fall of the Campanile at Venice.

No mention has been made up to the present time in these columns of the fall on July 14 of the famous Campanile at Venice. The reason for this silence has been the absolute lack of any definite information concerning the cause of the accident. The information received up to the present time which is most interesting is summarized below. The structure itself is too well known to need detailed description at this time. Its foundations date back nearly to 900. After 250 years it was probably nothing but a plain stalk surmounted by an arcaded belfry and a small spire. It is commonly considered only as the belfry of St. Mark's, but when its inferior style is contrasted with the architectural splendor of that famous church, it hardly seems as though it was much more than a monument of Venetian civic pride. Early in the sixteenth century its height was increased by a masonry box of large dimensions on top of the balcony, surmounted by a square spire and the whole topped with a 16-foot angel. It was about 320 feet high and always open, although no single visitor was allowed to ascend the inclined plane to the top. If a lone traveler wished to make the ascent, he was obliged to hire some one to accompany him. At the base of the shaft was a loggia or vestibule, a small structure built in 1540 by Sansavino, and a much more satisfactory work architecturally than the tower.

According to a paper in the library of the Institution of British Architects, the foundation of the tower was a carefully prepared base of stone blocks resting on the inevitable piling which carries all Venetian buildings. According to "The Builder," this foundation was ample to carry the weight of the structure. Nevertheless, for a number of years the city authorities have been warned from time to time that the structure showed signs of failing. As to the immediate cause of that failure, the reports received to date substantially agree with a statement by Mr. A. Robertson sent to "The Scotsman," on July 15, from which the following extract is taken:

Though the walls were thick, for they were only a few inches under 6 feet, they were really not solid. They consisted of two parallel walls of brick, the space (3 feet wide) between them being filled up with broken bricks, rubble, cement, stones, etc. Therefore the walls were not so strong as they looked.

The cement used was Istrian lime mixed with sea sand. This lime does not become hard, nor does it adhere well to the bricks. Indeed, in the course of the past centuries it became dry powder. It is all over Venice to-day. It formed the cloud that hid the falling Campanile.

It had been damaged by lightning, by fire and earthquake several times. On June 7, 1398, it was struck by lightning. In 1401, on the occasion of festivities for the Doge Michael Steno, fires were lighted on the platform, and the top was burned. On October 24, 1403, the same thing happened. In 1405 the same thing happened. In 1417 it was struck by lightning, and the new top of wood again burned. On June 21, 1436, all the shops round the Campanile built against it were burned. On March 26, 1511, an earthquake split its four corners. In June, 1548, it was struck by lightning. In 1565 it was struck by lightning. On July 10, 1591, an earthquake caused it to shake from top to bottom. In 1653 again struck by lightning. On August 23, 1657, again struck by lightning. On April 23, 1745, again struck by lightning, which damaged its east side severely, killing many people in the Campanile and near it. This was its last and most serious damage, although it was not till June 18, 1776, that the Republic employed the scientist, Guiseppe Toaldo, to put up a lightning conductor.

The Republic, seeing its east side to be severely damaged, consulted two engineers of fame and ability, Signor Zandrini, of Venice, and Signor Polene, of Padua, to examine and repair it. These engineers said the whole wall wanted support, and they proposed building a new wall against the old one. This was done. But the new wall was never properly tied to the old one. The two were practically separate, and so the weight of the Campanile was borne unequally and its equilibrium disturbed.

The ringing of the bells, the firing of artillery, and only three weeks ago the simultaneous firing in the Piazza of hundreds of muskets had a tendency to disturb it. Also the more or less frequent earthquakes that visit Venice.

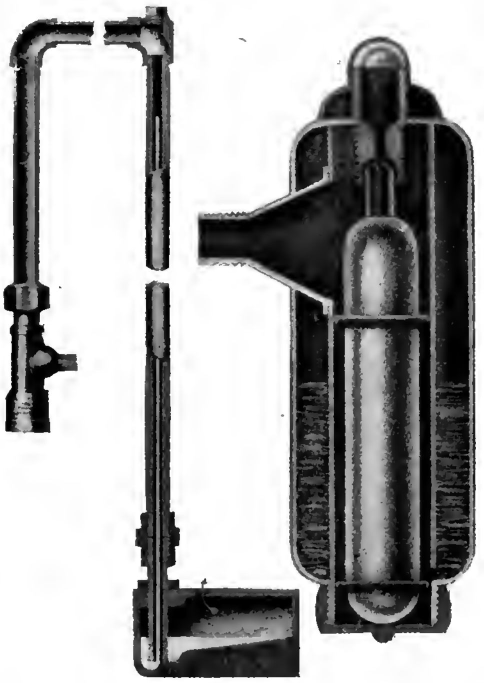
Twenty years ago one of the corner pilasters of the inner wall, and precisely that at the northeast corner, was seen to be cracked in many places. The authorities of St. Mark's Church, who have charge of the Campanile, as it is the bell-tower, had this pilaster tied up. No more cracks appearing anywhere, the Campanile was thought perfectly safe and was let alone.

And now comes the critical point. The Loggietta, little marble hall built by Sansovino, rests against the eastern wall of the Campanile. It had almost a flat roof. To prevent the rain beating against the Campanile and running down its side from entering this marble hall, a row of slabs of stone sloping downwards was inserted in the Campanile where the roof met it.

Only last week, that is, but ten days ago, these stones were begun to be removed, as the rain was somehow getting into the Loggietta, and a lead sheeting was to have been substituted. Instead of carefully removing one stone at a time, they removed half of them, that is 25 feet of them. Not only so, but they dug through the new wall of the Campanile, that of 1745, and struck the old original wall, which they found separate from the new, and full of holes and cracks. Whilst working, the old wall slipped down an inch or two. Instantly the cut made was built up, but it was too late. On Wednesday it was observed that the new wall was cracked at the northeast corner, above the Loggietta, where the work was begun. On Thursday it enlarged. On Friday it struck across the north side of the Campanile, sloping upward to the second window from the ground, then up to the third. On Saturday it passed behind the fourth and through the fifth. On Sunday the situation was, to use the word of an engineer, "desperate," and the Campanile was doomed. On Monday the crack visibly opened whilst we watched it, and the end came in a moment, when the whole structure sank into itself.

The Trane Vacuum Heating System.

A system of steam heating designed to operate with steam at a pressure below that of the atmosphere, without the use of any machinery or steam-actuated devices for the maintenance of a vacuum, was put on the market a short time ago by the James A. Trane Vacuum Heating Company, 40 Dearborn Street, Chicago. An essential feature of the system is the use of a mercury seal fixed to the outlet of the radiator air valve to prevent a return of air by that passage after it has once been expelled. Assured of the absence of air, the heating apparatus is depended on to produce such a vacuum as will be formed by the condensation of steam within the radiators, the non-existence of air within the radiators allowing for a circulation of steam throughout the plant at low pressures and consequently low temperatures. As the boiling temperature of water is less the greater the vacuum, the greater the condensation in this system the more rapid the generation of steam, since by the condensation the system is relieved of pressure; and on this account, it is considered that the fire in the boiler needs replenishing much less frequently, is accompanied with less waste heat, than with a low-pressure steam apparatus requiring higher temperatures.



An accompanying drawing shows the proportions of the mercury seal and the method of connecting to the radiator air valve. The pipe enclosing the mercury column is arranged ordinarily between the first and second columns of the radiator, so that the piping and seal are both hidden from view. One seal may be provided for each radiator or a system of air pipes can be carried to a convenient point, as in the cellar or basement, and a single seal connected to the air main. Assuming the radiator full of air on starting, the air has, of course, to be expelled as in any system, and passes through the mercury.

In connection with the seal, an ingenious air valve designed by Mr. E. P. Allen has been adopted by the Trane Company, as meeting the essential requirement of a tight valve. This is shown in an accompanying cross-sectional view. It consists of a shell connected to the radiator to form a well in the lower half of the valve, a sealed metal float placed in the well and a sealed outer chamber which is connected with the inner chamber by means of a small hole near the bottom of the inner shell. During the first operation of the valve the air in the radiator passes through the valve. When steam enters, the steam condenses, gradually filling the inner well with water, floating the sealed metal float to its seat, thus closing the valve. Five to ten minutes are allowed after steam enters in the first operation to condense sufficient water to carry the float. During this first operation the air in the outer chamber is expanded and more or less expelled through the small hole into the inner chamber and thence out of the valve through the regular outlet. As the inner chamber fills, the outer chamber becomes sealed by the water in the inner chamber. Since the air valve cools when steam is turned off, a vacuum is created in the outer chamber and the water in the inner shell is drawn into the outer chamber, allowing the float to drop, thus opening the valve. When steam again enters the valve, the heat expands the remaining air in the outer chamber and forces the water into the inner chamber, carrying the float to its seat.

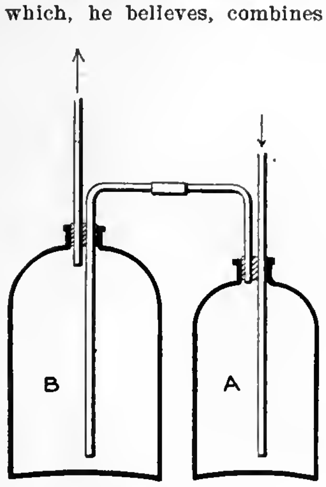
The various appliances manufactured by the company for the system are intended to be applied also to any low-pressure steam plant already constructed. Poorly constructed apparatus, it is asserted, will retain a vacuum of 10 to 20 inches for at least five to ten hours, and that the majority of steam plants of to-day, if supplied with the mercury seal, will be capable of maintaining a vacuum of 15 to 28 inches for 10 to 40 hours. A saving of 25 per cent. in fuel is claimed over the ordinary hot-water apparatus, with temperatures of radiators as mild as in the latter system of warming, and a still greater saving over low-pressure steam plants.

A New Engine is apparently languishing for lack of financial support; at least the following appeal in the columns of a New York daily would so indicate: "Wanted—Large capital to invest in an invention; a new motor (steam engine), no steam ejection, no condensator, directly rotative, complete utilization of latent heat, boiler stone and explosion absolutely impossible, permanent equal height of water in boiler, used steam returns to boiler, greatest reduction of fuel."

A Wheelbarrow is not generally considered a very difficult appliance to design properly, yet the average barrow certainly has features which can be improved. For example, a little while ago a gang of men was dumping earth from the end of a trestle. One of them tipped his barrow sidewise on the wheel guard, which slipped on the timber, and thus caused the fall of both man and barrow. It was some time before they could be brought up again and meanwhile six men were idle. This was a comparatively small matter, of course, yet it is the avoidance of these little things that spell success. In this particular case, the old barrows have been replaced by the type made by the Ellington Manufacturing Company, Quincy, Ill., which have the wheel guard so formed that it is possible to dump at either side or straight ahead.

An Apparatus for Collecting Samples of Water at Various Depths.

For many years chemists engaged in the sanitary analysis of water have recognized the value of the oxygen-dissolved determination as a rough indication of the condition of a ground water. The methods employed for securing samples for the usual analysis cannot be used for an oxygen-dissolved sample owing to the rapid absorption of the atmospheric oxygen by the water. The method generally employed for taking a sample for oxygen-dissolved consists in dropping a rubber hose into the water and, by means of a suction pump, forcing a stream of water into the bottom of the sample bottle. This process is continued until water amounting in volume to several times the capacity of the bottle has passed through it, thus washing out all water which has come into contact with the air. A second method, often used, consists in fitting a sampling bottle with two tubes. One, the inlet tube, extends to the bottom of the bottle and is carried through the stopper and about an inch above it. The other tube has its lower end just within the stopper and is connected with the open air by a rubber tube. Since there is no overflow possible, the sample has been in contact with the air in the bottle for a short time. Being under the necessity of taking a large number of samples for the determination of dissolved oxygen, Mr. Earle B. Phelps devised an apparatus for this purpose which, he believes, combines the advantages of the two methods without having their defects. He has described it substantially as follows in "The Technology Quarterly":



WATER SAMPLING BOTTLES.

The arrangement of the sampling bottle is shown in the accompanying diagram. A and B are two bottles of about 250 and 500 cubic centimeters capacity respectively, and are fitted with glass and rubber connections, as indicated. They are enclosed in a suitable weighted wire cage to which is attached a suspending cord with graduations indicating the depth. The method of operating is as follows: The cage containing the bottles is dropped quickly to the desired depth. The tube of the bottle B being higher than that of the bottle A, water will flow in through A and air pass out through B. A will be filled with water which will then overflow into B. When B is also full, which condition is shown by the cessation of air bubbles rising to the surface, A has been filled three times. The water which entered during the descent has all been washed over into B, and the water which A now contains has not been in contact with the air. Thus one obtains a fair sample of the water at the particular depth at which the determination is to be made. The cage is hauled to the surface, the rubber stopper removed, and a glass stopper quickly inserted. The reagents are then added as usual.

The temperature may be determined with sufficient accuracy in the bottle B after bringing it to the surface. A very convenient method for a more careful study of the temperature is to use in connection with this apparatus a Whipple thermaphone.

Although devised primarily for the collection of samples for the oxygen dissolved determination, this apparatus may be used for a variety of purposes. The writer has frequently used the water in the bottle B for the determinations of the micro-organisms.

It may appear that the bottle B is larger than an accurate determination requires. An experiment to determine this point was made as follows: A few drops of a strong solution of Fuchsine were added to the bottle A and a stream of water allowed to flow through the apparatus. By this means the actual course of the water through the apparatus could be easily followed. It was found that many eddy currents were formed and that A had to be filled at least three times before the dye was completely expelled.

Personal Notes.

Mr. George Hanson has resigned his duties as superintendent of the Texas & Pacific road to carry out some large contracts for the Missouri, Kansas & Texas R. R.

Mr. J. Z. George has resigned the duties of manager of the Vicksburg Electric Light & Railway Co., to become a partner of A. M. Lockett, New Orleans, in engineering and contracting work.

The following members of the Corps of Engineers, U. S. A., have been detailed to the General Service and Staff College at Fort Leavenworth: Capt. T. H. Rees, First Lieutenants George M. Hoffman and Gilbert A. Youngberg, Second Lieutenant W. Willing.

Mr. S. M. Swaab, Assoc. M. Am. Soc. C. E., has resigned his position as first assistant engineer on the work for the improvement, extension and filtration of the Philadelphia water supply to become assistant engineer on the staff of the Philadelphia Rapid Transit Co.

Messrs. Julian Kennedy of Pittsburg and Axel Sahlin of Cumberland, England, have formed a partnership for consulting practice in iron and steel production, under the name of Julian Kennedy, Sahlin & Co. Offices have been taken at 2 Norfolk St., Strand, London, and the reconstruction of several British iron works has already been entrusted to the firm.

Mr. W. B. Throop, recently appointed superintendent of the Aurora division of the Burlington system, was graduated from Cornell in 1877, and has been connected with the Burlington road since 1878. For about twelve years he was in the engineering and maintenance of way departments, and was then transferred to the operating branch of the service.

In order to celebrate properly the eightieth birthday of Mr. John Fritz, which will occur in a few months, it is proposed to raise by subscriptions of $10 each a fund to establish a medal to be awarded annually "to the originators of the most useful scientific or industrial achievements, in perpetual honor of John Fritz and to the glory of engineering." The committee of award is to consist of four members from each of the American national societies of civil, mechanical, mining and electrical engineers, but the recipients of the medal may be of any nationality. Many subscriptions have already been received, and it is confidently believed that the medal will be a distinction equal to the Bessemer gold medal of the Iron & Steel Institute. Subscriptions should be sent to the treasurer of the fund, Mr. John Thomson, 253 Broadway, New York.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvi, xvii, xviii and xxvii.

WATER.

Meridian, Miss.—Kirkpatrick & Johnson, of Jackson, Miss., have prepared plans for water works, and bonds to the amount of $150,000 for construction are reported to have been voted at the election held Aug. 2 and 4.

Hawkesburg, Ont.—The citizens have voted to raise $100,000 to install a modern system of municipal water works.

Oaxaca, Mex.—According to press reports, the Governor of the State of Oaxaca has offered a prize of $5,000 to any individual or company who will sink an artesian well. Andrew D. Barlow, Amer. Consul, Mexico City, Mex., may give further particulars.

Mamaroneck, N. Y.—Press reports state that the interurban Water Co. intends to construct a reservoir at Mamaroneck for the purpose of supplying Pelham and Mt. Vernon with an additional supply of drinking water.

Inglewood, Cal.—The Inglewood Water Co. has been incorporated; capital stock, $250,000. Directors: A. C. Freeman, P. A. Stanton, G. W. Van Alstyne, and others.

Morris, Ill.—It is stated that bids are wanted Aug. 12 for extending the water works. F. W. Ridgeway, City Clk.

Elgin, Tex.—Propositions for a system of water works and an electric light plant will be received by Chas. Gillespie, Mayor.

Mannington, W. Va.—B. E. Mitchell, Chmn. Water Com., writes that the contract for furnishing a quantity of cast iron pipe and specials, bids opened July 23, has been awarded to the U. S. C. I. Pipe & Fdy. Co., Cincinnati, for $4,000. Contract for labor, to G. R. Miner Const. Co., Salem, Wis., for $2,000.

Restraver Township, Pa.—The Restraver Water Co., Restraver Township, Westmoreland County, has been incorporated. Capital, $10,000. Directors: G. H. Craig, Allegheny; J. I. Martin, Beaver; M. R. Haymaker, Edgewood, and others.

Martinsburg, W. Va.—N. Wilson Davis is said to be preparing a report for the Water Bd. on proposed improvements.

Pittsburg, Pa.—The Common Council has passed a resolution providing for the appointment of a committee to secure an option on the plant of the Monongahela Water Co.

Pueblo, Colo.—The Trustees of the Pueblo water works have passed a resolution accepting the contract with the N. Y. Continental Jewel Filtration Co., of New York, when the price (which is said to be $114,000) is agreed upon, for a filtration plant having a capacity of 8,000,000 gal. per day.

Yonkers, N. Y.—The Bd. of Water Comrs. has received reports from 3 engineers in relation to increasing the city's supply of water. Wm. H. Baldwin, in his report, places the total cost of a system of natural sand bed filtration at $41,000; John A. Byrne in his report places the total estimated cost of natural filtration plant, capacity 3,600,000 gal. daily, at $35,633; and W. DeH. Washington in his report places the estimated cost of a sand filtration plant having a capacity of 4,000,000 gal. daily at $88,000.

Georgetown, S. C.—City Treas. J. Jenkins Hucks writes that on July 29 it was voted by a large majority to issue $75,000 bonds for the construction of water works and a sewerage system. J. L. Ludlow, of Winston, N. C., is reported to have prepared plans, etc.

Kenmore, N. Y.—Bids are wanted Aug. 15 for furnishing and laying cast-iron water pipe, as advertised in The Engineering Record.

Covington, Tenn.—Local press reports state that negotiations for the purchase of the water plant through arbitration having failed, the municipal authorities have formally notified the water company of their purpose to build a plant.

Sacramento, Cal.—The proposition to issue $150,000 bonds for the construction of new water mains in this city carried by a large majority at the election held July 24.

R. G. Hanford has submitted to the City Trustees a proposition from the North Fork Ditch Co. to supply the city with clear mountain water.

Upland, Ind.—The Town Bd. of Trus. has appointed a committee to investigate the advisability of putting in municipal water works.

Weatherford, Tex.—Consulting Engr. J. S. Thatcher, Dallas, writes in regard to bids opened July 28 by the City Council for furnishing material and labor necessary for the construction of a system of water works, that no bids were received on the entire work, so the Council concluded to withhold what bids were received, and will now receive propositions from manufacturers of pumps, boilers, hydrants and valves; the system to consist of a standpipe 14 ft. x 115 ft., a 70-H.-P. boiler, one 750,000-gal. duplex steam pump, one air compressor of 250 ft. per minute capacity, 50 double nozzle hydrants, 8-in. and 6-in. valves and boxes, about 6 miles of 6 and 8 in. pipe, power house and suction reservoir and 3 deep wells. Henry Miller, Mayor.

Mesa, Ariz.—City Clk. J. H. Pomeroy writes that this city proposes to construct water works, but plans and specifications have not yet been completed.

Redfield, S. D.—Bids are wanted Aug. 29 for extending the water mains. J. S. Huston, City Aud.

Ballard, Wash.—City Clk. J. Murdock writes that it is proposed to expend $10,000 in water main extensions. O. M. Rankin, Engr. in Charge.

Monticello, Minn.—Village Recorder W. J. Thompson writes that bonds to the amount of $10,000 were voted July 29 for water works and $4,000 for a gas plant.

Philadelphia, Pa.—Bids are wanted Aug. 12 for building Lardner's Point pumping station at the Torresdale filtration plant. Wm. C. Haddock, Dir. Dept. of Pub. Wks.

Washington, D. C.—Bids are wanted Sept. 6 for furnishing 30-in., 36-in. and 48-in. cast-iron water pipe and specials, as advertised in The Engineering Record.

Westerville, O.—Bids are wanted Aug. 19 for constructing water works, as advertised in The Engineering Record.

Charleston, S. C.—Bids are wanted by the American Pipe Mfg. Co., Philadelphia, Pa., until Aug. 15 for the construction of a combined earth and timber crib dam, timber lock, 2,000,000-gal. clear water basin and a 10,000,000-gal. settling basin, to be located about 11 miles from Charleston, as advertised in The Engineering Record.

Ellendale, Minn.—Village Recorder E. M. Thompson writes that on July 22 it was voted to construct water works.

Meadville, Pa.—The Council is considering the question of a pure water supply, but definite action has not yet been taken. A. C. Pardee, City Clk. W. A. Doane, City Engr.

Milton, Mass.—Bids are wanted Aug. 12 for the purchase of $315,000 bonds issued for the purchase of the property and rights of the Milton Water Co. J. Porter Holmes, Town Treas.

North Hempstead, N. Y.—Bids are wanted by the Town Bd., until Aug. 18 for furnishing a water supply for fire purposes to the Great Neck Water Dist., as advertised in The Engineering Record.

New Paltz, N. Y.—The New Paltz Water Works Co. proposes to build a reservoir. H. L. Griffis, Engr. in Charge.

Asheville, N. C.—City Clk. M. W. Robertson writes that it is proposed to install water meters. Bids will not be asked, but meters will be purchased direct from manufacturers as required. Wm. Francis, Supt.

East Rutherford, N. J.—Boro. Clk. Geo. A. Duncan writes that the question of constructing a municipal water and light plant is under consideration. W. W. Binning, Councilman.

Bloomington, Wis.—Press reports state that a water works and electric light plant is to be installed at once, at a cost of $16,000.

Elma, Wash.—The City Council has decided to build a reservoir and secure a new water supply.

Fonda, N. Y.—This village has voted to purchase the system of the Fonda Water Works Co. at a cost of $32,000.

Sulphur Springs, Tex.—Water works bonds to the amount of $20,000 were voted at the recent election.

Pennsgrove, N. J.—At the election held Aug. 5 a vote was taken in favor of the issue of $35,000 bonds for Boro. water works and electric light plants.

Muskogee, Ind. Ter.—Press reports state that the contract for a complete water works plant and sewer system has been let by this city to Allan Block & Co., of St. Paul, for $171,924. The work is to be completed June 15, 1903.

Colby, Wis.—The construction of water works and an electric light plant is said to be under consideration.

Cadiz, Ky.—The matter of establishing a water system is said to be under consideration.

Wonewoc, Wis.—Henry G. Strong is reported to have completed estimates for the $10,000 water system, for which bonds have been voted.

Houston, Tex.—The Texas Rice Development Co., of Houston, has been incorporated, to irrigate lands in Wharton and Brazoria counties; capital stock, $250,000. Incorporators: S. J. Johnson, D. C. Ritchie, A. C. Wilkinson and G. W. Huber.

Brookville, O.—The Council has passed an ordinance providing for the issue of $24,000 bonds for the construction of water works.

Springfield, O.—The City Council has concurred in the recommendation of Mayor Phillips for the construction of a dam at the water works pumping station on the river, and has directed the City Engr. to prepare plans and specifications and an estimate of the cost of said improvement. The Mayor has been authorized to communicate with various water meter manufacturers to secure prices, with a view to adopting a uniform meter system throughout the city.

Narberth, Pa.—The Town Council has decided to investigate the cost of establishing municipal water and electric light plants.

Great Falls, Mont.—This city has sold $45,000 water bonds, the money to be used in extending the water system and installing a subsidiary pumping plant.

New London, Wis.—At the election held July 29 it was voted to issue $35,000 bonds for water works and a power house.

Baraboo, Wis.—The Baraboo Water Works Co. having refused the city's offer of $85,000 for its plant, it is stated that the city will probably take steps at once for the construction of a municipal plant, $60,000 having been voted for same some time ago.

Stockton, Cal.—The stockholders of the Stockton & Mokelumne Canal Co. are reported to have voted $110,000 to enlarge and improve the Woodbridge irrigation system.

Ithaca, N. Y.—Plans for the dam to be erected in Six Mile Creek by the Ithaca Water Works Co. are said to have been completed and submitted to Consulting Engr. Geo. Y. Wisner, of Detroit, Mich., and Frank C. Osborn, of Cleveland, O., for approval.

Weiser, Idaho.—Bonds to the amount of $40,000 are reported to have been voted for water works and an electric light plant.

Manchester, O.—A committee of which S. S. Alexander is chairman, is making investigations with a view to installing water works and an electric light plant in this town.

Tucumcari, New Mex.—The Tucumcari Electric Light & Water Co. has been incorporated by Alexander D. Goldenberg, J. A. Street, C. H. Rankin and others. The capital is $10,000. The headquarters are at Tucumcari, Guadalupe County.

Farmington, Mo.—Bids will be received at the office of the Mayor until Sept. 4 for a brick pumping station; 2-H.-P. boilers and tank; a 50-H.-P. steam engine; 275,000-gal. pumping engine; 210 tons of pipe and specials, etc., as advertised in The Engineering Record.

Pittsburg, Pa.—Pres. J. F. Grimes, of the Chartiers Valley Water Co. is quoted as having stated that plans have been completed for a new pumping station, which the company proposes to build on the Monongahela River. It is stated that contemplated improvements will cost about $5,000,000.

East Liverpool, O.—The Bd. of Water Works Trus. is considering the installation of a filteration plant estimated to cost $50,000.

Greeley, Colo.—Ray Walters is said to be making a preliminary survey for a new source of water supply for this city.

Houma, La.—D. Angers, Town Clk., writes that bids will be received until Sept. 9 for constructing water works. Cost not to exceed $27,000. Geo. C. Morgan, Engr., Chicago, Ill.

Moline, Ill.—The Council has voted to adopt plans and specifications of D. W. Mead, of Chicago, for water works improvements, which provide for the installation of a 6,000,000 gal. pump, a mechanical filtering plant, settling basin and clear water basin of 5,000,000-gal. capacity. Estimated cost, $70,000.

Toledo, O.—Local press reports state that the Water Works Bd. is receiving bids for 300 tons of pipe.

Avon, N. J.—A certificate of merger and consolidation has been filed by the Avon Water Co. and the Wall Water Co., which were reincorporated as the Monmouth Water Co. The capital stock of the new corporation is $1,000,0000. The officers and directors chosen for the first year are: Pres., Oliver H. Brown, of Spring Lake; Vice-Pres., Cecil Campbell Higgins, of Bedford, N. Y.; Secy., James Steen, of Eatontown; Treas., Henry Campbell, of Eatontown, and Jasper Bray, of Point Pleasant.

SEWERAGE AND SEWAGE DISPOSAL.

Burlington, Ia.—City Engr. Emmet Steece writes that ¾ of a mile of 8 to 4-in. pipe sewer and about 2 miles of tile sewers will soon be ordered.

Dunkirk, N. Y.—Asst. City Engr. H. A. Holstein writes that bids for the Roberts Road sewer will not be opened before Aug. 16. The sewer is to be about 1 mile in length of tile, 20-in.

Evanston, Ill.—Comr. of Pub. Wks. J. H. Moore is preparing plans for drainage and sewerage of entire city. Larger portion of city is now sewered, but plan looks to future growth, also to relief of certain trunk sewers now overtaxed.

Defiance, O.—Bids are wanted Aug. 13 for constructing sewers in several streets. W. H. McClintock, City Clk.

New York, N. Y.—The Mayor has approved the resolution authorizing the issue of $100,000 bonds for the repair and reconstruction of sewers in the Boro. of Manhattan.

Washington, D. C.—Bids are wanted Aug. 30 for constructing sewers in the Dist. of Columbia, as advertised in The Engineering Record.

Rensselaer, N. Y.—The City Engr. has been directed to prepare plans and specifications for sewers to be constructed through Nelson and Riverside Aves. and Belmore Pl.

Ludwick, Pa.—Bids will be received by the Boro. Council until Aug. 18 for constructing a system of sewers in this borough. Specifications may be obtained at the office of the Greensburg Storage & Transfer Co.; R. J. Feightner, Boro. Secy.; J. J. Neel, Boro. Engr.

Havre, Mont.—Town Clk. S. T. Sanderson writes that on July 21 it was voted to issue $10,000 bonds for the construction of a sewerage system.

West Hartford, Conn.—Town Clk. Henry C. Whitman writes that A. B. Alderson, West Hartford, is the Engr. in Charge of proposed construction of sewerage system for the eastern part of town. Contracts for this work will probably be let this season. E. T. Stanley, Chmn. Bd. of Comrs.

Canton, O.—City Engr. Philip H. Weber writes that the following bids were opened Aug. 4 for the construction of sanitary sewers in Dist. No. 1: *a*, Section 1, including 4,430 ft. 18-in. pipe, 18 manholes, etc.; *b*, Section 2, including 750 ft. 15-in. and 3,220 ft. 18-in. pipe, 15 manholes, etc.; *c*, Section 3, including 1,520 ft. 10-in., 750 ft. 12-in. and 1,500 ft. 15-in. pipe, 14 manholes, etc.; M. A. Talbott & Co., Logansport, Ind., *a* $7,931, *b* $6,442, *c* $6,446; Geo. B. Herring & Son, Mansfield, O., *a* $7,815, *b* $6,732, *c* $6,306; McKinney & Son, Toledo, O., *a* $8,442, *b* $6,989, *c* $6,657; F. A. Piero, Canton, O., *b* $5,623, *c* $5,918.

Sanford, Me.—Town Clk. W. H. Wood writes that a survey has been made for a sewerage system, but it will not be built at present.

Mt. Clemens, Mich.—City Clk. Henry C. Benton writes that a brick sewer is to be built in Church St.; probable cost, $2,000.

Lockhart, Tex.—Mayor E. M. Storey writes that the contract for constructing a sewerage system (bids opened July 23) has been awarded to T. S. Hodges, of Gonzales, Tex., for $3,150. The contract calls for 3,450 ft. of 10 to 8-in. pipe sewers, 10 manholes, 4 catch basins and 1 flush tank; cut to average 6 ft. in depth and be excavated in black earth and gravel.

Atchison, Kan.—City Engr. Fred Giddings writes that the following bids were opened July 7 for the construction of sewers in Dist. C, South Atchison: Bidders—A, Hanley, McGuire & Wise, Leavenworth, Kan.; B, Rackliffe & Gibson, St. Joseph, Mo. (contract awarded); C, Chas. Crawford, Atchison; D, W. W. Cook & Son, Junction City, Kan.:

Items and Quantities.	A	B	C	D
Pipe sewers:

Totals	$42,966	$38,707	$40,028	$41,325

Note.—The price for curves and junctions each is in addition to the price per lin. ft. for sewer. Embankment is for filling over shallow sewers. The price per cu. yd. for rock excavation is in addition to the price per ft. for sewers in earth. Excavation is generally in clay, excepting for brick sewers 44 in. in diameter and over, which are laid in rock bed.

Lansing, Mich.—City Engr. H. A. Collar writes that plans for sewers in the 1st and 5th Wards call for most of the work in brick from 28x42 in. to 48x72 in., egg shaped, with some 8 and 10-in. pipe, in all 7,600 ft. Estimated cost, $23,000.

Boston, Mass.—Supt. of Streets Jas. Donovan will receive bids until Aug. 20 for furnishing and installing 6 boilers of 185 lbs. working pressure, at the sewer-division pumping station, Calf pasture, for the new 72,000,000 gal. pump. A bond of $10,000 is required and a certified check of $1,000 must accompany each bid. The boilers are to be of the horizontal, underfired return tubular type, having a length of about 18 ft. 5¼ ins. over all, and a least internal diameter of shell of 78 ins. Everything for building and installing the boilers is to be furnished by the contractor, excepting the steel plates for the boiler proper, which will be supplied by the city of Boston. The boiler must be tested before painting by water pressure to 300 lbs. per sq. in. E. D. Leavitt, of Cambridge, Mass., is Consulting Engr.; work must be completed by Jan. 25, 1903.

Sterling, Ill.—Press reports state that steps are being taken to establish a sewer system at a cost of $20,000.

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until Aug. 15 for constructing a joint district sewer in Tower Grove Joint Sewer Dist., embracing 2,260 ft. of 12.5x15 ft. brick and concrete sewer, with all necessary appurtenances, and for constructing joint district sewers, in Rock Spring Joint Sewer Dist., embracing 570 ft. of 10x12 ft. brick and concrete sewer, and 1,020 ft. of 10.5 ft., 310 ft. of 10 ft., 1,540 ft. of 8 ft. and 1,630 ft. of 7.5 ft. brick sewer, with all necessary appurtenances. Hiram Phillips, Pres.

Washington, D. C.—The Dist. Comrs. have ordered a trunk sewer laid in 13th St. S. W. at an estimated cost of $7,960.

Jersey City, N. J.—The Finance Com. has granted the request of the Street and Water Bd. for the following appropriations: $15,118 for sewer system in Belmont, Gardner, Monticello and Jewett Aves.; $20,000 for relief sewer in Division St.; $4,950 for relief sewer in Ocean Ave.; $5,635 for relief sewer in Harrison Ave., and $1,660 for relief sewer in Henderson St.

York, Pa.—Local press reports state that an ordinance providing for the establishing of a complete sanitary sewer system is about to be introduced in the Councils.

Georgetown, S. C.—See "Water."

Hartford, Conn.—Bids are wanted Aug. 13 for constructing Albany Ave. and Blue Hills sewer system, estimated to cost $33,000; also branch of intercepting sewer and New Park Ave. sewer system, estimated to cost $6,400; also a sewer in Tremont St. and across private lands to Smith St., estimated to cost $2,700. Joseph Buths, Pres. Bd. St. Comrs.

Brooklyn, N. Y.—Bids are wanted by J. Edw. Swanstrom, Boro. Pres., until Aug. 20 for furnishing material and constructing a sewer in Bedford Ave. Engr.'s estimate of the work is as follows: 9,795 lin. ft. of 36 to 96-in. brick sewer; 510 lin. ft. of 12, 15 and 18-in. stoneware pipe sewer, 69 manholes, etc.

Ft. Snelling, Minn.—See "Government Work."

Monticello, Ind.—It is stated that bids are wanted Aug. 19 for extending the Washington St. sewer. Webb P. Bushnell, City Engr.

Hawkesbury, Ont.—The citizens have voted in favor of the expenditure of $53,000 for a sewerage system.

Winnebago City, Minn.—Loweth & Wolff, of St. Paul, have been engaged to make a survey and prepare plans for a system of sanitary sewerage. J. Adams Armstrong, Village Recorder.

Perry, Ia.—Business men of this place are stated to have pledged $7,000 toward the construction of a sewerage system.

Loudonville, O.—The City Council has been petitioned by property owners to construct a sewer system.

Muskogee, Ind. Ter.—See "Water."

Paris, Ill.—Bids will be received by Z. T. Baum, Pres. of the Bd. of Local Improv. until Aug. 14 for constructing 5,000 ft. of 8 and 10-in. sanitary sewers, as advertised in The Engineering Record.

Peoria, Ill.—Bids are wanted by the Bd. of Local Improv. until Aug. 21 for furnishing material and constructing the Persimmon St. sewer system. Approximate estimates of the work are as follows: 420 lin. ft. of 2 ft. 2 in.x3 ft. 3 in., 430 ft. of 2 ft. 6 in.x 3 ft. 9-in., 425 ft. of 2 ft. 10 in.x4 ft. 3 in. and 440 ft. of 3 ft.x4 ft. 6 in. brick sewer; 6,610 ft. of 8 to 20 in. pipe sewer, 38 storm water inlet and 26 manholes. E. A. Furry, Chmn.; M. E. Beasley, City Engr.

Plainfield, N. J.—Local press reports state that bids will be received by the Common Council until Sept. 2 for constructing a system of sewers in the West End of the city.

Omaha, Neb.—City Engr. Rosewater has plans for a new roadway and sewerage system to be established in the northwestern part of the city.

Dunmore, Pa.—Sewer bonds to the amount of $35,000 have been sold by this Boro.

Girard, O.—The Mayor has been authorized by the Village Council to secure the services of an engineer to plan for the proposed sewerage system.

Eaton, Colo.—The Special Sewer Com. has reported to the Town Bd. that the estimated cost of a sewer system is $9,600.

Cincinnati, O.—City Engr. Stanley reported to the Bd. of Pub. Service that the proposed sewer in 8th, Wells and McPherson Sts. on Price Hill will cost $18,976.

Providence, R. I.—The Special Com. of the City Council is said to have completed arrangements for the construction of a 48-in. brick sewer from Blackstone Boulevard to Seekonk River.

West Seneca, N. Y.—It is proposed to construct a sewer estimated to cost $30,000 to drain the land east of the steel plant.

Lower Merion, Pa.—The following bids are stated to have been received for sewering Lower Merion Township: From Bryn Mawr to Ardmore—David Peoples, Philadelphia, $69,870; Jos. McGlathery, Philadelphia, $75,952; Acuff & Morehead, $76,858. Bala $60,328. Ardmore—Gill & Co., Philadelphia, $18,732; R. H. Johnson, Wayne, $23,179; Acuff & Morehead, $21,006. Ardmore to Rosemont—Land & Co., Philadelphia, $74,952; Acuff & Morehead, $76,838. Bala to Overbrook—David Peoples, $83,906; T. F. Reilley, Philadelphia, $88,153; Acuff & Morehead, $71,016.

Delray, Mich.—Sewer bonds to the amount of $65,000 have been sold by the Village Council.

New York, N. Y.—Bids will be received until Aug. 18 by Louis F. Haffen, Pres. of Bronx Boro., for constructing sewers in numerous streets. Engr.'s estimate of the work is as follows: 14,255 lin. ft. of 12 to 18-in. pipe sewers; 40 ft. of 3-ft. 6-in.; 225 ft. of 38x50-in., 225 ft. of 34x46-in. and 1,125 ft. of 26x36-in. brick sewers.

Clinton, Ia.—Local press reports state that the contract is about to be let for the construction of a combined storm and sanitary sewer on Margaret St.

BRIDGES.

Washington, D. C.—The War Dept. has approved plans submitted by the Bd. of Engr. Officers, for a bridge to be built across Potomac River, which will take the place of Old Long Bridge. Appropriation, $996,000. The structure is to consist of 11 spans, each 216 ft. long, and 1 revolving draw span, 290 ft. long. It is to have a double track for electric cars, granolithic sidewalks and an asphalt driveway.

Hillsboro, Tex.—Three steel bridges are reported to have been washed away by the freshets.

McKeesport, Pa.—The Common Council has approved the ordinance appropriating $7,440 toward the construction of a viaduct at Versailles Ave.

Zanesville, O.—F. M. Townsend is stated to have secured the contract to repair 3d St. bridge, for $5,950.

White House, Ky.—F. I. Cabell, Engr. of Construction of the Chesapeake & Ohio Ry. Co., has applied to the War Dept. for permission to construct a bridge across the Levisa Fork of Big Sandy River, about 6¼ miles above White House.

Barberton, O.—Wm. A. Johnston is said to be interested in the building of a viaduct across the canal at Tuscarawas St.

Lorain, O.—Press reports state that the Erie R. R. Co. will build a bridge in this city, to be 120 ft. long, and cost about $100,000.

Mifflinville, Pa.—C. H. Reimard, of Bloomsburg, is stated to have secured the contract to construct a bridge across Susquehanna River, at Mifflinville, for $93,985.

Columbus, O.—Local press reports state that the Pennsylvania R. R. Co. has filed plans and specifications for a steel bridge, which will replace the present bridge across Scioto River. Estimated cost $125,000. H. R. Leonard, Engr. of Bridges, Philadelphia, Pa.

Dyersville, Ia.—The Bd. of Superv. has voted to expend $5,000 for the construction of a bridge across Maquoketa River, in this city.

Brattleboro, Vt.—The Comrs. appointed by the towns of Brattleboro and Hinsdale (N. H.) have, according to reports, awarded the contract to construct a steel bridge connecting the 2 towns, to the United Construction Co., of Albany, N. Y., for $35,000.

Hornellsville, N. Y.—Damage amounting to $50,000 is reported to have been done by the recent freshets to bridges and highways in Canisteo township.

Springfield, Ill.—Plans and specifications are reported to have been received for the proposed viaduct to be constructed by the Chicago & Alton R. R. at Eastman Ave.

New Florence, Pa.—The citizens are considering the question of accepting the offer of the Pennsylvania R. R. Co. to construct either a tunnel or bridge at Ligonier St. Probable cost of work $20,000.

Perryville, Ark.—It is stated that bids will be received Aug. 20 for building a steel bridge, 280 feet long, over Fourche River. A. F. Leeghn, Co. Judge.

Houston, Tex.—Local press reports state that bids will be received by the Co. Judge until Aug. 14 for constructing a steel bridge, with wooden flooring, across Harris Bayou, at Main St.

Westchester, Pa.—It is proposed to build a stone arch bridge over Pigeon Creek in East Coventry Township, Chester Co., and specifications for same are being prepared by the Co. Comrs.

San Jose, Cal.—Bids are wanted by the Santa Clara Co. Bd. of Superv., Henry A. Pfister, Clk., until Aug. 18 for constructing a steel bridge or a concrete bridge over Carnendero Creek on the Monterey Road.

Brooklyn, N. Y.—Boro. Pres. Swanstrom has reported to the Bd. of Estimate & Apportionment in favor of building a $160,000 bridge across Gowanus Canal at Hamilton Ave.

Morgan, Tex.—Press reports state that 2 iron bridges on the Texas Central R. R., between this city and Fowler, have been washed away by freshets.

Binghamton, N. Y.—Bids are wanted Aug. 19 for a bridge to cross Park Creek at Cross St. I. C. Hull, City Clk.

Appleton, Wis.—City Engr. Chas. Vinal is reported to be preparing plans for a stone bridge, which it is proposed to build in place of the John St. structure.

Utica, N. Y.—The Owego Bridge Co., Owego, is stated to have received the contract to construct a bridge at Hancock St. for $6,822.

Indianapolis, Ind.—It is stated that the Lake Erie & Western R. R. will construct an iron bridge across White River, in this city. G. C. Cleveland, Asst. to Ch. Engr., Indianapolis.

Souris, Man.—The by-law to raise $8,000 for the building of a bridge in this city is reported to have carried.

Parkersburg, W. Va.—See "Electric Railways."

Santa Rosa, Cal.—The San Francisco Bridge Co. is stated to have submitted the lowest bid for building a bridge across Russian River, at Markham's, at $28,350.

Tarentum, Pa.—The Tarentum St. Ry. Co. has applied to the Council for permission to construct a bridge at Ross St.

Youngstown, O.—Co. Engr. Geo. Montgomery is preparing plans for a bridge to be built at Mahoning Ave. Probable cost $130,000.

Reports state that the Pittsburg & Lake Erie R. R. Co. has completed plans for a steel bridge, to be built in East Youngstown; estimated to cost $100,000. J. A. Atwood, Ch. Engr., Pittsburg, Pa.

Indianapolis, Ind.—Bids will be received by the Bd. of Co. Comrs. until Aug. 15 for constructing arch culverts on Kissell road, in Pike Township; for constructing roadway approaches to bridge over Swamp Branch, on Seerley road; for constructing an arch culvert on Seerley road, in Decatur Township; for constructing an arch culvert at intersection of Shelbyville and Bunker Hill roads, in Franklin Township. Bids will also be received until Aug. 29 for constructing a bridge across Pleasant Run, on East New York St. Harry B. Smith, Co. Aud.

Chicago, Ill.—See "Government Work."

Three Rivers, Mich.—The proposition to raise $15,000 to build a bridge across St. Joseph River is reported to have carried at the recent election.

Boston, Mass.—City Engr. Jackson will soon let the contract for the construction of the 3 remaining masonry piers for Broadway bridge over Fort Point Channel, two of the piers being at the channel and one at the S. Boston shore end of the bridge. About 40 of the 50 plans of the steel work for the superstructure are finished. These are exclusive of the draw. The appropriation for the bridge is $375,000.

The Metropolitan Water & Sewerage Board is stated to have awarded the contract for building steel bridges on the line of the central Mass. system of the Boston & Me. R. R., which is being relocated in Berlin and Clinton, to the American Bridge Co., of New York, for $91,450.

Akron, O.—The construction of a bridge at Cuyahoga St. is contemplated.

St. Charles, Ill.—An agreement has been reached between the city and the Elgin, Aurora & Southern Traction Co., whereby the Traction Co. is to construct a $26,000 concrete bridge, and the city is to pay $12,000 toward the cost.

Armour, S. D.—Bids will be received by John W. McKee, Co. Aud., until Sept. 1 for furnishing material and constructing 3 steel wagon bridges.

Parker, S. D.—Local press reports state that bids will be received by the Co. Comrs. until Sept. 3 for constructing a 70-ft. steel bridge. Jos. J. Waltner, Jr., Co. Aud.

PAVING AND ROADMAKING.

Muskegon, Mich.—Final estimates place the total cost of paving Lake St. at $35,193.

St. Joseph, Mo.—The House of Delegates has passed ordinance providing for the macadamizing of Dewey Ave. and the repaving with brick of a portion of 9th St. A resolution has also been adopted by the House of Delegates directing the City Engr. to test the relative merits of brick and asphalt as paving material.

South Bristol, N. Y.—This town is to be bonded to the amount of $12,000 for the repair of roads and bridges damaged by recent storm.

Oneida, N. Y.—City Engr. Wellington R. Vedder writes that bids will be received by this city until Aug. 21 for 39,000 sq. yds. of vitrified brick pavement.

Leavenworth, Kan.—About 22 blocks on Broadway will soon be paved with asphalt.

Marshall, Mich.—The proposition to issue $25,000 bonds for brick paving is reported to have carried.

Cincinnati, O.—The Bd. of Pub. Service has approved specifications for the improvement of Oregon St., partly with brick and partly with boulders. Estimated cost, $14,020.

Charleston, W. Va.—The City Council is reported to have awarded contracts for about 60,000 yds. of paving to Pfaff, Ringwald & Smith, of Chillicothe, O., their bids ranging from $1.46 to $1.66 for Requital block and $1.45 to $1.70 for Kanawha block; curbing at 55 cts. for Kentucky blue stone or 57 cts. for Berea stone. The total contract is said to amount to over $100,000.

Auburn, N. Y.—The contract for paving South St. with asphalt has been awarded by the Common Council to Warner-Quinlan Asphalt Paving Co., of Syracuse, at $1.84½ per sq. yd. Total, $31,365.

Ashland, Wis.—Press reports state that Second St. is to be paved with asphalt at once.

Three Rivers, Mich.—The proposition to issue $24,000 bonds for paving Flint Ave. and St. Joseph St. is reported to have carried by a large majority.

Cincinnati, O.—Bids are wanted Aug. 29 for the improvement of Taylor Ave. by grading, curbing and paving with brick. Robt Allison, Pres. Bd. of Pub. Service.

Williamsport, Pa.—Brandon Park Commission will receive bids until Aug. 20 for about 2,600 sq. yds. of macadam pavement. Plans, etc., can be seen at the office of Frederic A. Snyder, City Engr., Williamsport.

Washington, D. C.—The contract for paving with sheet asphalt (bids opened July 26), has been awarded to the Barber Asphalt Paving Co., at $1.56 per sq. yd., and the contract for asphalt block paving, bids opened at the same time, has been awarded to the Washington Asphalt Block & Tile Co. For bids received see The Engineering Record of Aug. 2.

Worcester, Mass.—The contract for furnishing 550,000 granite paving blocks has been awarded to Morse & Eagan, of Montpelier, Vt., at $1.45 per yd.

Crookston, Minn.—A resolution before the Council provides for the paving of about 33 blocks of residence streets with granite macadam.

College Point, L. I., N. Y.—President Cassidy, of Queens Boro., is said to be in favor of asphalting 13th St., the main thoroughfare of College Point. Estimated cost, $22,000.

Des Moines, Ia.—The City Council has passed over the Mayor's veto a resolution to pave East Walnut St. with asphalt, about 20,000 yds.

Lincoln, Neb.—City Engr. Campen's plans and specifications for repaving 2 districts have been approved by the City Council. Dist. No. 14, which is East O St., calls for 11,800 sq. yds. of brick work at $1.25 per yd., with 1 year guarantee, and 16,722 sq. yds. of asphalt at $1.60 per sq. yd., with 5-year guarantee, or $1.85 per sq. yd., with 10-year guarantee. Dist. No. 18, which is 7th St., calls for 5,500 sq. yds. of brick work at $1.20 per yd., with 1 year guarantee.

Niagara Falls, N. Y.—City Engr. Walter McCulloh has submitted his third set of estimates of the cost of paving Niagara Ave. The maximum cost of asphalt is given as $81,658, brick, $74,097, and macadam, $37,100.

Leavenworth, Ind.—Bids are wanted Aug. 16 for building a free turnpike on the Leavenworth and Marengo road, 6¾ miles in length. D. E. Wright, Comr. o fCrawford Co., English, Ind.

Washington, Pa.—The proposition to issue $30,000 paving bonds in East Washington Boro. is stated to have carried.

Waukesha, Wis.—Bids are wanted Aug. 29 for macadamizing McCall and Williams Sts. John P. Dey, Chmn. Bd. of Pub. Wks.

Hamilton, O.—An ordinance is reported to have been passed for the issue of $30,000 bonds for paving High St.

Jeffersonville, Ind.—Bids are wanted until Aug. 29 for the improvement of portions of several streets, with granitoid walks, vit. gutter, stone curb and macadam roadway. Victor W. Lyon, City Engr.

Council Bluffs, Ia.—City Engr. S. L. Etmyre writes that Pierce St. is soon to be improved by 3,000 ft. of artificial stone curbing and 5,500 sq. yds. of brick paving on a concrete base.

Ft. Worth, Tex.—Property owners on Houston St. are urging the City Council to have the street paved with asphalt.

Lowell, Mass.—City Engr. Geo. Bowers writes that the City Council has passed an order to pave with asphalt portions of 4 streets, in all 12,800 sq. yds.

East Windsor, Conn.—Bids will be received by the Bd. of Selectmen until Aug. 13 for constructing a macadam and telford road in the town. H. W. Talcott, 1st Selectman.

Muscatine, Ia.—Bids will be received by the City Recorder until Aug. 14 for grading, paving and curbing the streets and alleys in a part of improvement Dist. No. 20. Estimated quantities: Excavation, 7,000 cu. yds.; Ohio sandstone curbing, 5x20-in., 3,668 lin. ft., and 5x16-in., 2,400 lin. ft.; brick pavement on a 6-in. rock foundation, with 2½-in. top filler of sand, 11,196 sq. yds. Jas. J. Ryan, City Engr.

Dayton, O.—Bids will be received by the Bd. of City Affairs until Aug. 29 (readvertisement) for paving the roadway of Central Ave. with bituminous macadam or macadam, and for paving with bituminous macadam, brick or sheet asphalt, on Maple St., and for furnishing and setting the curbs. Estimated quantities: 12,970 sq. yds. of paving; 8,075 lin. ft. of straight curb, and 140 lin. ft. of circular curb. Robt. H. Ferguson, City Compt.

Glastonbury, Conn.—Bids will be received by the Bd. of Selectmen until Aug. 14 for constructing a macadam and telford road in this town. C. S. Loveland, 1st Selectman.

Cedar Falls, Ia.—The City Council on July 21 let the contract for paving and curbing certain streets, in all 17,454 sq. yds. paving, 4,200 lin. ft. of cement curb and 5,800 cu. yds. excavation to the Likes Improvement Co., of Des Moines, Ia., as follows: Paving with non-repressed brick on crushed rock foundations, $1.21 per sq. yd.; curbing, at 16 cts. per lin. ft.; excavation, at 16 cts. per cu. yd. An injunction was served on the Mayor and Councilmen on July 23 restraining them from entering into a contract with above company.

Washington, D. C.—The District Comrs. have ordered the roadway of I St. n. e. macadamized at an estimated cost of $6,800, and the roadway of B St. and Virginia Ave. n. w. macadamized at an estimated cost of $8,900.

York City, Pa.—The City Council has sold highway improvement bonds to the amount of $65,000.

Flint, Mich.—City Engr. A. W. Hall writes that the pavement of 3d St. East is being agitated.

Des Moines, Ia.—Bids are wanted Aug. 28 for paving with brick on Lyon St., in all about 11,097 sq. yds. John W. Budd, City Engr.

Camden, N. J.—The Co. Bd. of Freeholders has voted to construct a public road across the Meadows from Pleasantville to Camden. The estimated cost of the highway over 5 miles of marshland is $80,000, of which the State will probably pay $30,000.

Hawkesbury, Ont.—A vote was taken Aug. 4 in favor of expending $20,000 for street improvements.

New York, N. Y.—Louis F. Haffen, Pres. Boro. of Bronx, has awarded contracts for street improvements in the Bronx to the Barber Asphalt Paving Co. as follows: Forest Ave., at $1.02 a yd., $21,066; Park Ave., E. 165th St. to Tremont Ave., $1.02 a yd., $53,207; Washington Ave., 3d Ave. and 159th St. to Pelham Ave., $1.28 a yd., $135,739; Washington Ave. intersections, $1.28 a yd., $7,558.

Milwaukee, Wis.—Bids are wanted Aug. 12 (readvertisement) for furnishing material and repaving the roadway of 16th St. viaduct with creosoted pine blocks. Chas. J. Poetsch, City Engr.

Memphis, Tenn.—Bids will be received by the Bd. of Fire & Police Comrs. until Aug. 29 for paving portions of numerous streets with asphalt. Local press reports state that there will be in all about 151,000 sq. yds., and that the probable cost will be about $225,000. W. B. Armour, City Secy.

New York, N. Y.—Bids will be received until Aug. 18 by Louis F. Haffen, Pres. Bronx Boro., for grading Grant Boulevard and Concourse, from E. 181st St. to Mosholu Parkway, and constructing temporary roadways, sidewalks and paths. Engr.'s estimate of the work is as follows: 298,000 cu. yds. of earth excavation, 402,000 cu. yds. of rock excavation, 603,000 cu. yds. of filling, 14,100 cu. yds. of random range ashlar faced masonry in retaining walls, 170,000 sq. yds. of macadam pavement, 33,300 sq. yds. of paved gutters, etc. Bids will also be received at the same time for regulating and grading, setting curbstone, flagging sidewalks, etc., on portions of numerous streets. Engr.'s estimate of the work is as follows: 21,720 cu. yds. of earth excavation, 29,350 cu. yds. of rock excavation, 82,315 cu. yds. of filling, etc. Bids will also be received until Aug. 18 for paving and repaving with asphalt on portions of several streets, in all about 39,890 sq. yds. of new pavement and 32,610 sq. yds. of stone pavement to be relaid as foundation, or in approaches, etc.

Medford, Wis.—Bids will be received by J. H. Wheelock, City Clk., until Aug. 16 for constructing 3,117 ft. of cement curb and gutter, 9,400 sq. yds. of macadam, 3,063 ft. of 6, 8 and 10-in. water mains, etc. W. G. Kirschoffer, Engr., Baraboo, Wis.

Paris, Ill.—Bids will be received by Z. T. Baum, Pres. Bd. of Local Improv., until Aug. 14 for 15,200 sq. yds. of brick paving on a concrete foundation, 2,000 lin. ft. of stone curbing and 6,100 lin. ft. of combined curb and gutter, as advertised in The Engineering Record.

Wapakoneta, O.—The City Council has decided to sell $30,000 bonds for street and highway improvements.

Toledo, O.—Bids will be received by the Bd. of Co. Comrs. until Sept. 3 for constructing stone roads Nos. 36 and 37 by grading, draining, bridging and macadamizing the same. Wm. M. Godfrey, Co. Aud

Duluth, Minn.—City Engr. W. B. Patton writes that the following bids for paving East Superior St. were opened July 25: Western Construction Co., Lafayette, Ind., Trinidad Lake asphalt, $65,000; Western Paving & Supply Co., Indianapolis, Ind., Trinidad Lake asphalt, $55,446; Barber Asphalt Paving Co., New York, Trinidad Lake asphalt, $54,760; Warren Bros. Co., Boston, Mass., Warren's bituminous macadam, $50,280.

New York, N. Y.—The Sicilian Asph. Pavg. Co. has been awarded 19 contracts for an aggregate of 45,570 sq. yds. of asphalt paving on present pavement relaid as foundation, the tendered price for asphalt being $1.05 per sq. yd. and the price for relaying, 25 cts. per sq. yd.; total amount, $83,253. Contracts were also awarded to the Barber Asph. Pavg. Co. on bids received at the same time, July 29, for 12,420 sq. yds., total $25,176, and to the Asphalt Const. Co., for 4,920 sq. yds., total, $9,771.

Bids were also received for granite paving on concrete foundation, the N. Y. Sand & Gravel Co. being awarded a contract for $5,424, involving 1,470 sq. yds. of granite block, and Cunningham & Kearns, a contract for $7,450, involving 2,100 sq. yds.

Detroit, Mich.—The contract for furnishing asphalt block for the resurfacing of John R. St. has been awarded to the Lake Erie Asphalt Block Co. at $1.90 per sq. yd It is estimated that 5,080 sq. yds. of asphalt blocks will be required.

City Engr. Ferguson writes that the lowest bid received July 24 for paving a portion of Wabash Ave. with cedar block on a 6-in. concrete foundation was from H. Merdian, Detroit, as follows: 6,796 cu. yds. excavation at 30 cts.; 8,210 lin. ft. Berea straight curb at 48 cts.; 172 lin. ft. Medina circles, 95 cts.; 12,817 sq. yds. paving, $1.22 per sq. yd.; 224 cu. yds. curb concrete, at $2.50. Total, $22,393.

POWER PLANTS, GAS AND ELECTRICITY.

Washington, Ia.—Bids are wanted Aug. 26 for constructing a municipal electric lighting plant. Hugh H. McCleery, City Clk.

Atlanta, Ga.—A. H. Cox, Attorney, representing the Atlanta Electric Co., has petitioned the City Council for a franchise. This company proposes constructing a dam on the Chattahoochee River and generating the power for electrical purposes.

Jordan, Minn.—Bids are wanted Aug. 23 for $6,000 electric light bonds. C. Roderig, City Clk.

Indianapolis, Ind.—Bids are wanted Aug. 19 by the Bd. of Trus. for the installation of 2 500-H.-P. water tube boilers for the Central Indiana Hospital for Insane. Archt., Adolf Scherrer, Indiana Trust Co. Bldg.

Beatrice, Neb.—Bids are wanted Aug. 16 for the construction of an electric light and power house. Address Geo. A. Berlingh, Beatrice.

Globe, Ariz.—C. M. Clark is reported interested in the construction of a power plant on Salt River, directly north of Globe. It is estimated that it will furnish 6,000 H. P., enough to supply the town of Globe and the surrounding mining camps.

St. Louis, Mo.—Bids for the annual contract for lighting municipal buildings will be received by the Bd. of Pub. Improv. until Aug. 15.

National Military Home, Kan.—Bids are wanted Aug. 25 for the extension of the electric light plant at Western Branch, N. H. D. V. S. Maj. W. W. Martin, Treas.

Monticello, Minn.—See "Water."

Los Angeles, Cal.—H. H. Sinclair, Gen. Mgr. Power Development Dept., Edison Electric Co., writes that a power plant is to be constructed on Kern River. Estimated cost—hydraulic installation, $860,000; electrical installation, $800,000. Partial contracts will be made from time to time. F. C. Finkle, Engr. in Charge.

Manchester, Mass.—There is talk of constructing an electric light plant. The committee which has investigated the matter has recommended the establishing of a plant to cost about $150,000.

Evanston, Wyo.—The Edison Electric Co. has been incorporated, with a capital of $10,000,000. The company proposes to establish a power and light plant in the vicinity of Evanston and in the Uinta oil fields. It will also build and operate electric railways, furnish power to run drills and pumps in the oil fields, and also transmit power to distant mining camps. Andrew Cooke and Peter A. Fagg are among the incorporators.

Pueblo, Colo.—The Pueblo Gas & Fuel Co., of Pueblo, has been incorporated to construct, acquire, purchase and lease gas works, manufacture and lay pipes for the purpose of supplying the city and county of Pueblo, with gas for illuminating and other purposes; capital, $300,000. Directors: T. E. Eyman, J. D. Taylor and C. H. Prall, of Pueblo.

Farson, Leach & Co. and Devitt, Tremble & Co., Bankers, of Chicago, Ill., are reported to have purchased the plant of the Pueblo Gas Light Co. for $500,000. It is the intention of the new owners to expend several hundred thousand dollars in enlarging and extending the plant, and to reorganize the finances of the company.

Findlay, O.—The Kerr Mfg. Co., of Ft. Wayne, Ind., is stated to have secured the contract for an artificial gas plant for the Citizens Gaslight & Htg. Co., for about $60,000.

Buffalo, N. Y.—The Twentieth Century Acetylene Gas Co. is reported incorporated, with a capital of $100,000, to construct an acetylene gas plant. Jas. A. Roberts, Pres.; Jos. B. Roberts, Secy.

Plainview, Minn.—T. G. Bolton, Arthur Koenig and F. J. Cornwell are stated to have secured a franchise for an electric light plant. They have purchased a plant located at Durand, Wis., and will remove it to this place.

Ephrata, Pa.—Thos. A. Wilson is stated to have purchased the old grist mill on the Cloister premises and will establish there an electric light plant, to supply Ephrata and the surrounding county with light.

Monroe, Wis.—The City Council is stated to have granted the Chicago Bldg. & Mfg. Co., of Chicago, Ill., a franchise for a gas plant.

Great Falls, Va.—The Water Motor & Power Co. is reported to be planning to erect a large power house at Great Falls. The Co. has been organized to supply power to manufacturing plants. It was recently incorporated in Del., with a capital of $1,000,000. The incorporators include several prominent men of Washington, D. C.

Nashville, Tenn.—Duncan & Waddey, Real Estate Agents, are stated to have sold a tract of land in the 19th Dist. to the Cumberland Mfg. Co. The company proposes constructing an electric plant there when the lock is completed by the Government. The plant will furnish electrical power to the city.

Lampasas, Tex.—The Lampasas Light & Power Co. has been incorporated; capital $15,000. Incorporators: B. F. Barnes, F. J. Harris and others.

Ord, Neb.—The Council is stated to have passed an ordinance granting the Ord Light & Fuel Co. a franchise to construct and operate gas and electrical works.

Richmond, S. I., N. Y.—Arthur Corliss, of Brooklyn, Benj. R. Seaman, of Elizabeth, N. J., and Robt. P. Barry, Jr., of N. Y. City, are directors of the Richmond Light Co., just incorporated, with a capital of $3,000,000, to carry on operations in the Boro. of Richmond.

Talladega, Ala.—The Talladega Co. is stated to have purchased the city gas plant. The company proposes to generate 5,000 H. P. at Jackson's Shoals, 8 miles from the city, and operate an electric power, light and traction plant. It is proposed to run a car line from Lincoln to Ironaton, passing through and encircling the city of Talladega.

Kankakee, Ill.—The Council has granted franchises to the Citizens Gas Co. and to the Kankakee Electric Co.

Denton, Md.—L. B. Towers is reported interested in the construction of an electric light plant.

Navarre, O.—Geo. A. Myers, of Massillon, is stated to have secured a franchise for an electric light plant in Navarre.

Narberth, Pa.—See "Water."

Rhinelander, Wis.—Thos. A. Taylor and associates are stated to have secured a franchise to construct and operate an electric light plant.

Weiser, Idaho.—See "Water."

Dell Rapids, S. D.—The business men and citizens are reported to be discussing the matter of providing a local electric light plant. Whether it shall be established by the city or by a company has not yet been determined.

Manchester, O.—See "Water."

Pittsburg, Pa.—The Shadyside Electric Co. is stated to have applied for a charter to organize a company to furnish light, heat and power to the residents of the East End district. Wallace H. Rowe, W. L. Abbott and Alan W. Wood are said to be interested.

Columbus, O.—Bids are wanted Aug. 18 for furnishing labor and material for constructing an electric light plant for the city. Perry Okey, Supt. of Lights, has on file plans and specifications, which provide for 3 cross compound condensing engines of 500 H.-P. each, at 150 revolutions; 2 condensers, 3 400-Kw. steam turbines and generators; 4 horizontal water tube boilers, 300 H.-P. each; 1 176x9 ft. steel chimney; fuel economizers; 3 500-Kw., 2 phase, 60 cycle alternating current generators; and 1,500 7.5 ampere series alternating enclosed arc lamps. Clarence M. Addison, Clk. Bd. Pub. Wks.

New London, Wis.—See "Water."

Knoxville, Tenn.—The Knoxville Gaslight Co. will extend its mains to Oakwood addition; about 1 mile of 6-in. mains and 3 or 4 miles of laterals.

Elgin, Tex.—See "Water."

Susquehanna, Pa.—The Susquehanna County Electric Co. is reported incorporated, with a capital of $30,000.

Colby, Wis.—See "Water."

Albuquerque, N. M.—J. J. Henry and T. B. Whitted, of Denver, Colo., are stated to have purchased a controlling interest in the Albuquerque electric light plant and the city gas works. It is reported that a large sum will at once be expended in improvements. It is also reported that they may decide to build an electric railway in Albuquerque.

Penngrove, N. J.—See "Water."

Indianapolis, Ind.—The City Council has passed an ordinance ratifying the franchise recently granted the Citizens' Heat & Light Co.

Bloomington, Wis.—See "Water."

Kenmore, N. Y.—The citizens are stated to have voted Aug. 5 to install pipes, lamp posts and burners required for a complete gas lighting system, at a cost not to exceed $5,000.

East Rutherford, N. J.—See "Water."

Dexter, Mich.—Bids will be received by A. Davis & Co. until Aug. 20 for constructing an electric light and power plant for furnishing street and commercial lighting in this city.

Columbus, Ga.—Stone & Webster, 93 Federal St., Boston, Mass., write that they have decided to build a dam across Chattahoochee River at Columbus. It is not intended to construct a new power station.

ELECTRIC RAILWAYS.

Prospect, O.—The Columbus, Delaware & Marion Electric R. R. Co. will construct a branch line from Prospect to Richwood, a distance of about 6 miles. H. A. Fisher, Gen. Mgr., Columbus.

Covington, Ky.—A charter has been granted to the Sandy Valley & Elkhorn Ry. Co., of Kenton County; capital, $50,000. The road will start from a point opposite Ironton, O., and run through Greenup, Boyd, Lawrence, Johnson, Floyd, Pike and Letcher Counties in Ky. Incorporators: L. C. Goodale and F. L. Hoffman, of Cincinnati, O., and Frank Sullivan, of Covington.

Indianapolis, Ind.—Local press reports state that the Indianapolis Traction & Terminal Co. has secured a franchise for the erection of passenger and freight terminal stations and the construction of downtown loops. The following 8 companies are also reported to have secured franchises: The Union Traction, the Indianapolis Northern, the Greenfield, the Greenwood, the Shelbyville, the Martinsville, the Plainfield and the Lebanon Traction.

New Philadelphia, O.—The Massillon & New Philadelphia Electric Ry. Co. has been incorporated, with a capital of $600,000, to construct a line from Navarre to New Philadelphia. Incorporators: Dr. E. C. Lewis, of Canal Dover; Jno. C. Welty, of Canton, and others.

Winona, Minn.—A survey is being made by Geo. P. Brandis for an electric line from Winona to Rushford, a distance of about 28 miles. The Winona Ry. & Light Co. is supposed to be the promoter of this scheme.

Ridgway, Pa.—A charter has been granted to the Elk County St. Ry. Co., with a capital of $126,000, to construct a line 21 miles long from Ridgway to Johnsonburg, Rolf St. Marys and other places. Incorporators: Walter S. Ravenscroft, Ridgway; Edw. H. Yaeger, Pittsburg, and others.

Atlantic City, N. J.—The Camden, Atlantic City & Chelsea Passenger Ry. Co. has been incorporated with a capital of $250,000, to construct an electric railway in and about Atlantic City. Kane S. Green, Rosemont, Pa.; Wm. B. Schofield, Camden, and Louis Knehnle, Atlantic City, are among the incorporators.

Anderson, Ind.—Gus M. Hodges, of Dayton, O., is negotiating for a right of way for an electric railway between Anderson, Ind., and Newcastle.

Toledo, O.—It is stated that the Toledo Ry. & Light Co. will expend about $75,000 in improving the facilities of the company in this city. The first step will be the construction of car shops and storage sheds on Central Ave. A. E. Lang, Pres.

Cleveland, O.—Bids are wanted Aug. 25 for the construction and operation of street railways in numerous streets, separate bids having been asked for routes Nos. 1, 2, 3, 5, 6, 7, 8, 9 and 10. Bids are also wanted Aug. 28 for constructing and operating street railway route No. 4. Chas. W. Toland, City Clk.

Riverside, Cal.—Local press reports state that the City Trus. have made certain amendments to the proposed franchise for an electric road asked for by the San Bernardino Valley Traction Co., and that the time for receiving bids for same has been extended to Sept. 2.

Bolivar, N. Y.—The Town Trus. are stated to have granted a franchise to the Olean Electric Ry. Co.

Whitehall, N. Y.—The Vermont & Whitehall Ry. Co. has been incorporated, with a capital of $500,000, to operate an electric railway 9 miles long from Whitehall to the Vermont State line, to intersect the proposed route of the Rutland St. Ry. Directors: David A. Slattery and Ronald K. Brown, of N. Y. City; Ezra A. Tuttle, of Brooklyn, and others.

Tipton, Ind.—The Union Traction Co. is reported to have secured a site for the erection of a power plant at Tipton. G. F. McCulloch, Gen. Mgr., Anderson.

Batavia, N. Y.—The Buffalo & Depew Electric Ry. Co. is about to petition the Council for a right of way through Batavia. John T. Mooney, Supt., Depew.

Pueblo, Colo.—The Rapid Transit Co. has been incorporated to construct an electric line to Beulah, about 28 miles west of the city. Chas. Henkel, Pres.; J. J. Burns, Secy.

Evanston, Wyo.—See "Power Plants, Gas and Electricity."

New Albany, Ind.—The New Albany St. Ry. is reported to have passed to the control of the syndicate which now owns all the lighting, heating, traction and water properties of New Albany and Jeffersonville. It is stated that about $75,000 will be expended for improving the street railway.

Chestertown, Md.—The Baltimore & Chestertown R. R. Co. has been incorporated, with a capital of $75,000, to construct an electric railway from Chestertown to Rock Hall and Tolchester Beach. Incorporators: Henry R. Fothergill, Wilmington, Del.; Harcourt N. Trimble, Philadelphia, Pa., and others.

Clarkston, Mich.—The Council is stated to have granted J. A. Randall, of Detroit, a franchise for an electric railway to be constructed from Pontiac to Clarkston.

Canastota, N. Y.—The Canastota & Morrisville Ry. Co. is stated to have secured franchises in Canastota and Sylvan Beach. Wm. H. Patten, Pres.

Urbana, Ill.—The Danville, Urbana & Champaign R. R. Co. is reported incorporated, with a capital of $250,000, to construct an electric railway from Danville through the counties of Vermillion, Champaign, Platt, Macon and Sangamon, to Springfield. Principal office to be at Urbana.

Ossining, N. Y.—The Highway Comrs. are stated to have granted a franchise to the Westchester Traction Co. to construct its road to the town line of Ossining.

Fowler, Colo.—The Otero Interurban Light, Power & Traction Co. is reported to be circulating petitions among property owners preparatory to asking the Town Council for a franchise to operate a railway over the streets of Fowler. The company proposes to build an electric line across Otero County from west to east.

Warsaw, Ind.—The City Council is stated to have granted a franchise to the Winona, Warsaw, Elkhart & South Bend Traction Co.

Ft. Smith, Ark.—The Ft. Smith Suburban Ry. Co. has been incorporated, with a capital of $100,000, to construct a belt line 6 miles in length. Geo. Sengel, Pres. S. A. Williams, Secy.

Talladega, Ala.—See "Power Plants, Gas and Electricity."

Galesburg, Ill.—The City Council is reported to have granted a franchise to the Galesburg & Kewanee Electric St. Ry. Co.

Mayfield, Pa.—A charter is stated to have been granted to the Mayfield, Carbondale & Crystal Lake Ry. Co., to construct a line from Mayfield through Carbondale to the lake.

Salt Lake City, Utah.—The Co. Comrs. are stated to have granted a franchise to the Salt Lake & Suburban Ry. Co.

Parkersburg, W. Va.—The Parkersburg Bridge Terminal Ry. Co., of Parkersburg, W. Va., has been incorporated to build a railway in Wood County, W. Va., and in Washington County, O., and to construct bridges across the Ohio and Little Kanawha Rivers. Incorporators: J. T. Blair, Greenville, Pa., and B. S. Bacher and H. J. Cook, of Parkersburg.

Methuen, Mass.—The Selectmen are stated to have granted a franchise to the Lawrence & Methuen St. Ry. Co.

Sharon, Pa.—The Sharon & West Middlesex Electric R. R. Co. has been incorporated, with a capital of $50,000, to construct a line from Sharon to West Middlesex.

Viroqua, Wis.—The City Council is stated to have granted a franchise to the La Crosse & Eastern Ry. Co.

Paris, Ill.—The Paris & Terre Haute Traction Co. has been incorporated to construct a railway from Paris to various cities in Edgar and Champaign Counties; capital, $5,000. Incorporators: Geo. W. Hughes, Hume, Ill.; Henry H. Knipe, Marshall, Ill.; Joseph D. Hunter, Paris, and others.

Youngstown, O.—The City Council is stated to have granted a 25-year franchise to the Pennsylvania & Mahoning Valley Electric Ry., to construct a line on Mahoning Ave. to the National Steel plant. The line will connect with the system of the company throughout the city. E. M. Scofield & Co., of New York, N. Y., are stated to have secured the contract for constructing the superstructure of a power house to be erected by the Pennsylvania & Mahoning Valley El. Ry. Co. in the eastern part of the city. Contract price reported to be $40,000.

Milan, Ill.—The Western Illinois Electric Ry. Co. has been incorporated, with a capital of $15,000, to construct an electric railway connecting the lower end of Rock Island County and Aledo, in Mercer Co. Incorporators: Franklin H. Caldwell and Elmer E. Reynolds.

Souderton, Pa.—The Souderton, Skippack & Fairview Electric Ry. Co. has been incorporated, with a capital of $100,000, to construct a line through Harleyville, Skippack, Centerpoint and Fairview, a distance of about 17 miles. E. S. Moser, Pres., Collegeville; B. W. Dambly, Secy., Skippack.

Bound Brook, N. J.—Ch. Engr. H. M. Herbert, of Bound Brook, writes that a company is being organized to construct the Watchung Scenic Ry. between Plainfield and Bound Brook; length of proposed road, 10 miles. Surveys have not yet been completed, but the probable cost is placed at $200,000.

Parkesburg, Pa.—The Boro. Council is stated to have granted a franchise to the West Chester St. Ry. Co.

Cleveland, O.—The Cleveland & Sharon Traction Co. has been incorporated, with a capital of $10,000, by Thos. C. Willard, Chas. W. Dille, and others, to construct an electric railway connecting Cleveland with Sharon, Pa., and passing through Cuyahoga, Geauga and Trumbull Counties.

Albuquerque, N. M.—See "Power Plants, Gas and Electricity."

Roslyn, L. I., N. Y.—The Mineola, Roslyn & Port Washington Traction Co., of Roslyn, has been incorporated, with a capital of $150,000, to operate an electric road 10 miles in length. Directors: Isaac H. Odell, Fred. H. Parker, and others, of N. Y. City.

RAILROADS.

Huntington, Ind.—Huntington Township is stated to have voted a subsidy of $78,500 to the Dayton, Union City & Huntington R. R. Co.

Montreal, Que.—A press report states that the Canadian Pacific Ry. Co. will expend about $200,000 in reconstructing its yards at North Bay. David McNicoll, Gen. Mgr., Montreal.

Lake Charles, La.—Bids are wanted for grading 25 miles of Southern Pacific R. R. at Lake Charles. Address S. A. Robertson, Orange, Tex.

Hoxie, Ark.—The St. Louis, Memphis & Little Rock R. R. Co. has been incorporated, with a capital of $1,250,000. The road will begin at Hoxie and run a distance of 125 miles through Craighead, Jackson, Woodruff, Prairie and Lonoke Counties to Little Rock. F. E. Blomeyer and F. E. Burroughs are among the directors.

Morris, Ill.—The Chicago, Rock Island & Pacific R. R. Co. is reported to be making a survey for a new line from Morris to St. Louis, Mo., by way of Bloomington. W. E. Danchy, Ch. Engr., Chicago.

New Athens, Ill.—The Okaw Valley R. R. Co., of New Athens, has been incorporated, to build a line from Vanedy Station to New Athens: capital, $10,000. Incorporators: Chas. Stroh, New Athens; Geo. C. Probst, Nashville, Ill., and others.

Rochester, N. Y.—A press report states that W. J. Wilgus, N. Y. City, Ch. Engr. N. Y. Central & Hudson River R. R., has completed plans for the double-tracking of the Falls division, between Rochester and Niagara Falls; the improvement will cost about $200,000.

Autaugaville, Ala.—A charter has been granted to the Autauga R. R. Co. to construct a railroad from Autaugaville to Booths or Prattville; capital, $100,000. S. M. Dinkins, Pres., Montgomery. M. M. Smith, Vice-Pres., Autaugaville.

Clayton, Mo.—The St. Louis, Clayton & Olive St. R. R. Co. is stated to have petitioned the Co. Comrs. for a right of way through St. Louis County. D. C. Taylor, Pres.

Cherryvale, Kan.—A charter has been granted to the Cherryvale & Texas Ry. Co. to build 900 miles of road from Cherryvale, Kan., through Independence and Caney, Kan., and the Cherokee, Osage and Ponce Indian reservations to Perry, Okla. Ter., where one line will be constructed to El Paso and another via Pawhuske, Okla., to Paris, Tex.; capital, $18,000,000.

Nashville, Tenn.—Hunter McDonald, Ch. Engr. of the Nashville Chattanooga & St. Louis Ry., writes that preliminary surveys only have been made for proposed extensions in Wilson, Cannon and DeKalb Counties.

Superior, Wis.—The Superior Suburban R. R. Co. has been incorporated to construct and operate a railroad 100 miles long within Douglas County; capital, $25,000. Incorporators: John A. Bardon, Wm. J. Leader, and others, all of Superior.

Corbin, Ky.—Col. L. F. Hubble is reported interested in the construction of a railroad from Corbin to Celina, Tenn.

Jefferson City, Mo.—A charter has been granted to the Memphis & Chicago Ry. Co., with a capital of $200,000, to construct a railroad through Cape Girardeau and Scott Counties, Mo. R. T. Booth and W. B. Drake are among the incorporators.

San Augustine, Tex.—L. J. Smith, of Kansas City, has secured the contract for constructing 20 miles of railroad from San Augustine to Center.

Orange, N. J.—A press report states that the Lackawanna R. R. Co. has prepared plans for the elevation of its tracks through Orange and will present them to the Common Council at an early date. W. K. McFarlin, Ch. Engr., Hoboken.

Riparia, Wash.—The contract for building the line of the Oregon R. R. & Navigation Co. on the north bank of the Snake River between Riparia and Lewiston, is reported to have been awarded to Mr. Wren, of Spokane, and Mr. Greenough, of Missoula, Mont. Work to begin at once and to be completed by April 15th. There are 71 miles of road to be built, and this contract covers grading and bridging for the whole line, involving about $800,000.

PUBLIC BUILDINGS.

Portland, Me.—Frank W. Cunningham is stated to have secured the contract for erecting the city home for $112,450.

Cincinnati, O.—The Directors of the House of Refuge are about to petition for an appropriation of $50,000 for additions to the institution.

Springfield, Ill.—Bids will be received by S. A. Bullard, Archt., 208 S. 6th St., until Aug. 13 for furnishing material and erecting the Prentice M. E. Church.

Boston, Mass.—Bids will be received by the Trus. of the Boston City Hospital until Aug. 14 for installing a ventilating and heating system in Pavilion 3. A. Shuman, Pres.; Jas. Mulcahy, Archt., 66 State St.

Hennepin, Ill.—Bids are wanted Aug. 25 for erecting a brick Catholic church. Rev. F. Gahlman, Pastor.

Hartford, Conn.—The Hartford Co. Senators and Representatives are stated to have voted an appropriation of $90,000 for an addition to the court house, the installing of new boilers and for electric lighting of the buildings.

Lawton, Okla. Ter.—Bids will be received by the Bd. of Co. Comrs. until Aug. 25 for erecting a court house. Sam Frances, Chmn.

Houston, Tex.—Plans, specifications and detailed drawings will be received by D. D. Bryan, City Secy., until Oct. 6 for a combined market house and city hall. Cost not to exceed $100,000.

Ottawa, Ont.—Bids are wanted Aug. 23 for the construction of the Mint at Ottawa. Fred Gelinas, Secy. Dept. of Pub. Wks.

Buffalo, N. Y.—Bids are wanted Aug. 14 for the erection of a 1-story brick lavatory, to be located on the grounds of the Elk St. Market; also for sundry alterations in the tower of Clinton Market Bldg., to be used as a lavatory. Francis G. Ward, Comr. of Pub. Wks.

Jackson, O.—Bids are wanted Aug. 21 for an addition to and repair of the Jackson Co. Court House. C. P. Schellenger, Co. Aud.

Eureka, Cal.—Geo. A. Kellogg, Secy. Bd. of Trus., writes that the contract for constructing the Carnegie Library has been awarded to A. N. Foster, of Eureka, Cal., for $20,842.

Louisville, Ky.—J. H. Cowles, Clk. of Fiscal Court, writes that D. X. Murphy & Bro., 250 5th St., have been selected to prepare plans for the Jefferson Co. Jail, estimated to cost $196,000.

Pasadena, Cal.—The plans of C. H. Brown, of Los Angeles, are stated to have been accepted for a city hall, to cost $34,000.

Portland, Ore.—The contract for constructing a dry dock has been awarded to Robt. Wakefield, of Portland, at a compromise bid of $162,000.

Osceola, Ark.—Bids are wanted Aug. 20 for dredging about 13 miles of drainage canal, involving the removal of about 223,000 cu. yds. of earth. Address John A. Fox, Osceola.

Greenville, Miss.—Bids will be received by the Bd. of Miss. Levee Comrs. until Aug. 25 for constructing about 800,000 cu. yds. of levee work. Nathan Goldstein, Secy.

Boston, Mass.—The following bids were opened July 31 by the Boston Transit Commission for part of Section D, East Boston Tunnel. The dates given are the time of beginning and the time of completing, respectively: A, Jones & Meehan, Boston, $141,555, Aug. 11, 1902; Apr. 11, 1903; B, Metropolitan Cont. Co., Boston, $131,555; Aug. 9, 1902; Dec. 31, 1902; C, P. McGovern, Roxbury, Mass. (awarded), $126,310; Aug. 11, 1902; Feb. 11, 1903. For detail bids see accompanying table:

Items and Quantities.	A.	B.	C.
12,000 cu. yds. earth excav.	$7.00	$7.15	$6.40
3,500 cu. yds. concrete, Port. cem. mortar	14.50	11.40	12.00
30 tons steel rods, etc.	25.00	18.00	100.00
Laying vit. pipe:			
20-in., 560 lin. ft.	1.50	3.50	2.50
15-in., 60 lin. ft.	1.50	3.00	2.25
1,500 sq. yds. coating Port. cem. mortar	1.00	1.10	.75
1,500 sq. yds. tarred felt, pitch, etc.	.50	.25	.75
500 cu. yds. clay boxing	5.00	1.85	1.00
Per cent. on $1,500 worth extra work	25	15	15

NEW INDUSTRIAL PLANTS.

The John Davis Co., 51-79 Michigan St., Chicago, will erect a new plant.

The Columbus, O., Buggy Co. proposes erecting a new plant, which will include three 4-story, 300x100-ft. buildings of mill construction equipped with sprinklers and elevators on the outside of the building. The power plant will include 1,000 H.-P. in boilers, engines and generators. The factory will be operated by electric motors and wood-working and wheel machinery, steam drop hammers, etc., will be installed.

The Chesapeake Development Co., of Baltimore, has been organized with a capital of $1,500,000 to reclaim the timber lands of southern Maryland, using the timber for railroad ties, lumber and fuel. The company wants to correspond with makers of portable saw-mills. Jas. E. Brady, 104 E. Lexington St., Baltimore, Treas.

The Pfaudler Co., 67 Fort St., East, Detroit, Mich., is erecting a plant at Rochester, N. Y., for which two 150-H.-P. boilers served by a brick stack, engines, electric generators, motors, shafting, etc., will be required.

T. E. Nash, Grand Rapids, Wis., is interested in the erection of a saw-mill, and will soon be in the market for machinery, including boilers, engines, shafting, pulleys, etc.

The Butz Fire Plug Co., Piqua, O., expects to erect a 150x75-ft. foundry and a machine shop 75 ft. square.

BUSINESS NOTES.

The Phoenix Iron Works, Portland, Ore., are erecting a 60x80-ft. foundry, a 2-story, 70x100-ft. machine and boiler shop and a 30x50-ft. pattern shop and expects to be ready for business in about six weeks.

The Otis Elevator Co., New York, reports receiving the following orders: Manhattan Ry. Co., four heavy electric passenger elevators equipped with magnet controlling devices for the new station at 110th St. and Eighth Ave., New York; General Electric Co., Schenectady, N. Y., seven electric elevators with Otis motors and controllers; hydraulic plunger automobile lift for stable of Miss Helen Gould, New York; 51 electric elevators and 15 hydraulic elevator equipments.

A new addition to the power plant of the Lewis Institute, Chicago, will consist of a 150-H.-P. engine built by the Ball Engine Co., Erie, Pa., direct connected to a 75-Kw. generator.

G. H. Gest, 277 Broadway, New York, has been awarded the contract for additions to the underground subway system of the Edison Electric Illuminating Co., of Brooklyn.

During the past six months the firm of H. R. Heinicke & Co., No. 160 5th Ave., New York, has completed large brick chimneys for Ware Furniture Mfg. Co., Atlanta, Ga.; Philadelphia Pneumatic Tool Co.; American Snuff Co., Yorklyn, Del., and Kittatinny Hotel, Delaware Water Gap, Pa., and is now at work on similar stacks for Powers & Weightman, East Falls of Schuylkill, Philadelphia, Pa., and the Housatonic Mfg. Co., New Haven, Conn.

The Crocker-Wheeler Co., Ampere, N. J., is increasing its floor space by a new building, which will nearly double the present capacity, permit placing new and heavier machinery to accommodate larger generators and more rapid work on large orders for the smaller standard machines. The new building is of brick, slow burning mill construction, 3 stories in height and intended for the winding departments and light machine tools. A portion of the basement space will be used for experimental laboratories.

The National Biscuit Co., Baltimore, is installing an electric plant, consisting of two 300-H.-P. cross-compound Ball engines direct connected to General Electric generators.

For the Susquehanna Iron & Steel Company's new plant at Columbia, Pa., the Pittsburgh, Pa., Gage & Supply Co. will furnish three 250-H.-P. water-tube boilers. The company has also recently received the following orders: National Steel Co., White Star filtering system for vertical cross compound blowing engines; filtering systems for the Electric Department of the Carnegie Steel Co. Homestead Works, and the Wheeling, W. Va., Steel & Iron Co.

Westinghouse, Church, Kerr & Co. have under fulfilment a number of important contracts for railway, lighting and power properties, including the following: Metropolitan Street Ry., Third Ave. Division, designing Kingsbridge station and installing boiler, engine, condenser and generator equipments; Meriden, Conn., Electric Light Co., remodeling lighting plant, rebuilding and extending boiler and engine room, and installing an entire equipment of new machinery; Lackawanna & Wyoming Valley R. R., designing and constructing one of the most important high-speed interurban roads in the country; American Car & Foundry Co., Berwick, Pa., erecting a car manufacturing plant; Rochester, Auburn & Syracuse Ry., design and construction; Pittsburg & Lake Erie Ry., McKees Rocks, Pa., mechanical equipment for large railroad shops and terminal station; Champion Coated Paper Co., Hamilton, O., and American Smelting & Refining Co., extensive high-pressure steam piping outfits; Nikola Tesla, Wardenclyffe, N. Y., electrical equipment, steam engines, auxiliary apparatus, steam piping, etc.; Walter W. Law, Briar Cliff Manor, N. Y., electrical heating and refrigerating outfits for suburban isolated plant and villa; Phipps Residences, New York, mechanical, electrical, heating and refrigerating outfits for isolated plant.

THE ENGINEERING RECORD.
Volume XLVI., Number 7.

TABLE OF LEADING ARTICLES.

Progress in Civil Engineering.................. 145
The New Croton Dam. (Illustrated.).......... 146
The Water Supply of the Michigan Asylum for the Insane at Kalamazoo. (Illustrated.)........ 148
Two Recent Water-Power Plants on the Arve River, France 150
Tests of Special Properties of Mortar.......... 150
The Rock Creek Concrete-Steel Arch, Washington. (Illustrated.) 151
A Solid-Floor Single-Track Plate-Girder Bridge. (Illustrated.) 152
The Mechanical and Electrical Equipment of the Pittsburg & Lake Erie Railroad Terminal, Pittsburg.—II. (Illustrated.) 152
Cellar Bracing in the New York Stock Exchange. (Illustrated.) 155
An Important Decision Concerning River Pollution by Sewage.......................... 157
The Glendive Highway Bridge................ 161

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Progress in Civil Engineering.

In his presidential address before the Institution of Civil Engineers, from which extracts have already been printed in The Engineering Record, Mr. Charles Hawksley indulged in a very interesting retrospect covering the progress of civil engineering during the nineteenth century, some portions of which are particularly worthy of consideration in view of what civil engineers have accomplished in this country. Mr. Hawksley naturally confines his observations chiefly to the parts which British civil engineers have played in the development of their profession. This is not only pardonable on the part of the president of the Institution of Civil Engineers but justified by a number of epoch-making accomplishments of the early civil engineers of Great Britain, especially in connection with the development of common roads, the steam engine and railroads.

It is interesting to observe the broad meaning which Mr. Hawksley attaches to the term Civil Engineer, and most important in view of what he would constitute or form the early training of all engineers whom he calls "civil," but who, in the specialized condition of engineering in this country, would be considered as civil, mechanical, electrical and a considerable number of other specialists in engineering practice. As a matter of fact, Mr. Hawksley's position in this matter is historically accurate, and it would probably be better both for the educational training and the general profession of civil engineering in this country if the significance of the broad expression still ruled both in our engineering schools and in our engineering practice. Be that as it may, however, in his consideration of the advances made along all engineering lines the eminent president of the Institution takes a commendably enlightened view of the practice of the profession, and one, it is believed, from which few or no practicing engineers will dissent.

Among the various fields of work which he outlines as having been exploited practically during the nineteenth century, that of "Roads" comes first, and it is first because of the importance attaching to that class of engineering works in the past development of Great Britain. The same general observation is equally applicable to the subject of canals, which comes second in his order of treatment, the third being that of railroads. While we, in this country, have recognized the importance of means of transportation and the exchange of commodities between communities, it was almost at the close of the nineteenth century that the improvement of our common roads came to be recognized in its true character. As a matter of fact, it is of equal importance with the development of railroads. Indeed if our improved common roads had been developed to the extent justified by their real importance they would have become a system of numberless feeders to the railways, not only increasing the value of the latter but giving to the sections of country served enhanced values far beyond those which they now possess.

The construction of steam railroads in this country gave such a stimulus to many branches of industry that the value of common roads and canals has been overlooked, and it is only within a short time that the true part played by both those classes of transportation has been recognized. To some extent, but to a small extent only, has there been a corresponding attitude assumed toward roads and canals in Great Britain. It is perhaps generally conceded now, on the other hand, that the three classes of transportation are not mutually excluding but co-operating elements in the most complete and well-rounded prosperity of any country.

It would have added much to the interest of Mr. Hawksley's retrospect if he had compared some of the modern locomotives and trains to those first used on the Stockton and Darlington Railway in 1825 and 1826. He speaks of the first engine built by Robert Stevenson as weighing 14,560 pounds, whereas a recent locomotive of the decapod type, built for the Atchison system, has a total weight of almost 268,000 pounds, or over eighteen times the weight of its English prototype. A comparison, also, of the weights of the earliest trains with those now being hauled in this country, would be equally interesting and marked. The early railway train was, in fact, but a system of a half a dozen stage coaches drawn along an artificially prepared track as a speed of perhaps eight to ten miles an hour. At the present time in this country it is not uncommon for a modern locomotive to haul a freight train of 2,000 or more tons at what would have been considered a good passenger speed three or four decades ago.

Similarly interesting and significant advances have been made in all lines of civil engineering practice, although that in the special field of electrical engineering shows probably a greater rate of advance in a short period than any other. Among those other fields of engineering work to which Mr. Hawksley calls attention, one of the most striking is possibly that of public water supply. He shows the remarkable progress which has been made, not only through the past century, but during the past fifty years, in serving municipalities with potable water. It was scarcely more than fifty years ago when the appalling conditions of many English manufacturing towns was disclosed by a parliamentary committee, those conditions being due primarily to the absence of suitable water supply, and, secondarily, to the proper disposition of waste products of the community. All that has, of course, been radically changed, and there now exist in Great Britain the most advanced views in regard to public water supplies and the means of securing and maintaining them. It has come to be recognized that no intermittent supply, or one of limited proportions, will answer the needs of a modern English community, any more than it will in this country. Yet a comparison of the figures of daily consumption in the two countries reveals a marked difference which has been the subject of much discussion among civil engineers. Mr. Hawksley observes that "there still exists much misconception in regard to the quantity of water required for domestic purposes with a constant service, unrestricted except in respect to misuse and waste." He goes on to say that as a result of his professional experience he has found that "water distributed for domestic and other nonmetered purposes was," in six towns containing about 1,185,000 persons supplied by private companies, 19 gallons per head per day, "and in the case of ten towns supplied by public authorities and having an aggregate population of 3,961,000 persons, 18¼ gallons per head per day." In this country, where a corresponding supply is supposed to amount to anywhere from 80 to 100 gallons per head of population per day, the English figures seem remarkably small. All civil engineers recognize that in many cities where the consumption rises materially above those figures, as much even as two-thirds of the supply may be waste of one kind or another. Admitting that, however, there still remains a large difference between the English figures and those of American consumption to be explained. Undoubtedly much of this difference in useful consumption arises from the different habits of the two peoples. In this country water is far more lavishly used in the household for bathing and other purposes than in foreign countries, and while there is doubtless some extravagance in the American practice, it is not by any means impossible, indeed it is probable, that the latter is, on the whole, more conducive to improved or better conditions of life. Again, a rather marked feature of Mr. Hawksley's observations upon public water supplies is his apparent preference for the private ownership of municipal water systems or at any rate, his failure to agree with those who prefer municipal ownership. It is a question about which there are certainly two opinions in some quarters in this country.

The whole address of Mr. Hawksley is one abounding in interesting retrospects of British engineering works suggesting comparisons with corresponding American work of at least equal interest. In every respect it is a most timely and pertinent review of engineering progress during the past century, on which both British and American engineers may reflect most profitably, not only in regard to their own practice, but each one in relation to the other.

The Assuan Barrage across the Nile just above the first cataract has been practically completed, a fact that is not only of much engineering interest but also of still more importance in the broader world of commerce. The barrage was so fully described in The Engineering Record of December 30, 1899, that a further account of it is unnecessary in this journal. It is a great masonry weir pierced with 180 openings which are fitted with gates. From August until December the Nile is laden with silt, which would not only speedily choke the reservoir were the stream impounded during these months, but would also cut off from the agricultural lands below the fertilizing deposit which renews their surface during each year and renders them productive to a marvellous degree. Early in December the gates will be closed and for five or six months the flood water will be impounded to be used in irrigating until the rise in the river, beginning sometime during the next July, again furnishes a natural supply to the farmers. The work is the first great material step in the commercial regeneration of this home of primitive civilization to which Great Britain has set her hand.

The New Croton Dam.

Preliminary work on the new Croton dam was commenced in the fall of 1892 and more than three-fourths of the masonry had been laid when, in the summer of 1901, it was decided to modify the design and a part of the work was interrupted for several months. In accordance with the report of a commission of experts, which was published in The Engineering Record of November 30, 1901, it was decided to replace the embankment at the south end by a massive masonry structure which is essentially an extension of the main dam into the solid rock of the hillside. This involves the removal of that portion of the dam which had already been built on this side of the valley and the construction of about 60,000 yards of ashlar and rubble masonry more than was originally contemplated. The work on the north end of the dam is now under full headway, that for the removal and rebuilding of the south end is being vigorously prosecuted and in the middle of the valley a portion of the dam is completed to its full height. These conditions afford comprehensive illustration of the varied operations, some of which are of interest to supplement the extended accounts of work on the structure previously published in these columns.

The original design was for a masonry dam with a straight axis and a length of about 710 feet on top, with a 1,000-foot masonry spillway tangent at the north end, curving nearly 90 degrees and continuing upstream along the hillside approximately following the contours. At the south end a rubble core wall was bonded into the masonry structure and carried down to solid rock in a trench cut in the hillside to the top of the dam. This core wall was protected by flat slopes of rolled earth on both sides, which terminated with a wing wall on the downstream side. The masonry section crossed the river bed and its foundations were carried down to a maximum depth of 135 feet below it. It has a curved batter on both the up and downstream faces, as is shown in the illustrations published in The Engineering Record of August 11, 1898. The spillway is built in steps from 3 to 9 feet high on the downstream face.

About 32,000,000,000 gallons of water will be impounded by the dam and form a lake about 19 2/3 miles long and 130 feet deep at the dam, and will submerge 3,425 acres of farm land, several houses and roads, of which the latter are to be replaced by others now under construction. The base of the dam is about 216 feet in maximum width and the crest is 144 feet above the top of the back-fill on the upstream side or 300 feet above the lowest part of the foundations. There will be a 20-foot roadway on top with a stone parapet on each side and a gate house at each end. The original quantities included 1,100,000 yards of earth, 300,000 yards of rock, 670,000 yards of masonry and 900,000 yards of backfill and embankment at an approximate total cost of about $5,000,000. The core wall and the heart of the masonry dam and spillway are made of large rubble masonry laid in Portland cement mortar. The faces are dimensioned quarry-faced granite stones up to 80 cubic feet, in courses from 20 to 36 inches high. The coping, cornice, gatehouse trimmings, etc., are cut stone.

The spillway and the main dam section were not changed by the modification of the design, but all of the earth and core dam at the south end was ordered replaced by a continuation of the regular section of the masonry dam. This involved the removal of about 10,000 yards of rubble core wall masonry and the excavation of about 300,000 yards of earth, some of which had been backfilled around the core wall, and an unknown amount of rock to carry the foundation down to sound rock. About 60 feet of the upper part of the wing wall will be removed, but the remainder will be allowed to stand as it will be below the surface of the finished slope.

On the south side of the valley the main dam has been carried up to its full height and practically finished for a length of about 700 feet. Cut stone arches of 19 feet span have been built there on the top of the downstream face and surmounted with the coping and cornice, ready for the final cresting of stone railing along the roadway. A concrete elliptical sewer, about 4½ feet wide and high is built on top of the dam under the center of the roadway and receives the latter's drainage through transverse inlets and discharges into the spillway on the downstream side. From the top of the completed section the masonry is racked off to lower levels at both ends.

At the south end a small timber tower is seated on top of the masonry and carries one end of the 700-foot Lidgerwood cableway with a head tower on the hillside. The north end of this main cable enters a deep slot cut in the solid masonry and engages a steel cross bar built into the masonry which is farther loaded by a large quantity of dimension stone piled on top. The cableway is only about 10 feet above the top of the dam and is used at present for removing the materials of the core wall as it is demolished. About 80 feet east of this cableway is a 1,150-foot cableway with its north tower seated on the dam near the spillway, and about 75 feet west of the first mentioned cableway, which is nearly in the axis of the dam, is a cableway of 1,465 feet span with its north tower on the side of the hill beyond the spillway channel. Both these last two cableways were manufactured by the Trenton Iron Company and have been used chiefly for delivering stone to the masons and will be used for the same purpose for the lower part of the additional work.

View Looking North.

The lowest parts of the main cables are about 130 feet above the river bed and so are unable to handle materials for the top of the dam. Up to their highest working level the masonry was laid by as many as thirty independent stiff-leg derricks with 40 to 60-foot booms of 5 to 10 tons capacity operated by individual two-drum hoisting engines of the Lidgerwood, Crook, Mundy, Ryan & McDonald and Donegan & Swift makes. Each derrick built up the masonry within its convenient radius to a height of 15 feet above its base and was then, with its engine, picked up by the cableway and set on top of the upper part of the masonry, and so on.

On the finished part of the dam one stiff-leg derrick is now seated at the roadway level to handle the arch and cornice stones, and for any other work to be done there. North of it there is a traveler seated on two 3-foot longitudinal tracks about 15 feet below the roadway. It has a horizontal framed platform about 20 feet wide and 30 feet long and has three masts, one in the center of the upstream side and one in the center of each end. The masts are braced together and to the platform, which is heavily ballasted, and each has a 10-ton boom. The side boom is used for hoisting stone and mortar from the material tracks on the upstream side of the dam about 150 feet below its crest. The end booms build the masonry, one of them carrying it up to the roadway level and the other one building it to the level of the traveler tracks, which are extended northward on it as it rises. North of this traveler there are two more which are similar to it except that they have no side booms. One is 45 feet below the top of the dam, and the other is in use on the spillway; each builds 15 feet below its track on one side and 15 feet above it on the other, and when they have completed their zones they will be removed.

All the stones in the faces of the dam must conform to the required course thicknesses but may vary within limits in their other directions. They are numbered consecutively at the contractors' granite quarry about six miles away, and about 32,000 have so far been cut. Each stone has its number marked on it with red paint and its dimensions in black paint, and a record is kept of the dimensions, when the stone was cut, by whom and when it was set in the dam. The coping stones are carefully fitted and their joints are calked with oakum and pointed with cement.

The quarry track comes down the valley at an elevation about 10 feet above the river bed at the dam and an opening was left in the upper part of the spillway wall to let it pass through and another for it to pass to the lower side of the main dam. The latter opening is about 20 feet wide and 20 feet high, with a full-centered brick arch roof 2 feet thick. The stones in the dam which form the sides of this tunnel are set slightly oblique to its axis so as to make offsets of 3 to 6 inches at each joint and prevent the formation of any continuous water passage when the masonry is eventually filled in solid there. The roof arch is also offset 6 inches at two places in transverse planes for the same purpose, which incidentally provides a very great shearing resistance for the pressure on the filling. A similar opening 26 feet wide and 18 feet high is left in the line of the river diversion to pass the water until the dam is completed, when a cofferdam will be built on the upstream side, and masonry will be filled in solid and grouted under pressure. An extremely heavy flood last winter proved to be too much for the waste opening and filled it and the track opening and backed up to a height of 2 feet above the top of the track and 12 above the river tunnel, but did not cause much damage.

The excavation for the extension of the masonry dam which will replace the earth and core-wall dam will be about 150 feet deep and is being made by four crews of shovelers and one 1½-yard steam shovel. All spoil is loaded into 2½-yard side-dump cars and drawn by locomotives to spoil banks 1,000 feet or more upstream, where it is dumped down the side of the valley. The steam shovel is working on a wide berm about 70 feet above the bed of the river and at the foot of a very steep bank about 70 feet high. The material is sand and gravel with a small amount of clay, cemented to a very hard bank which will stand almost vertical. When wet it washes down and makes a dense sticky mud which, when dried, pulverizes easily and is so fine that it leaks badly through the cracks of the steam shovel bucket.

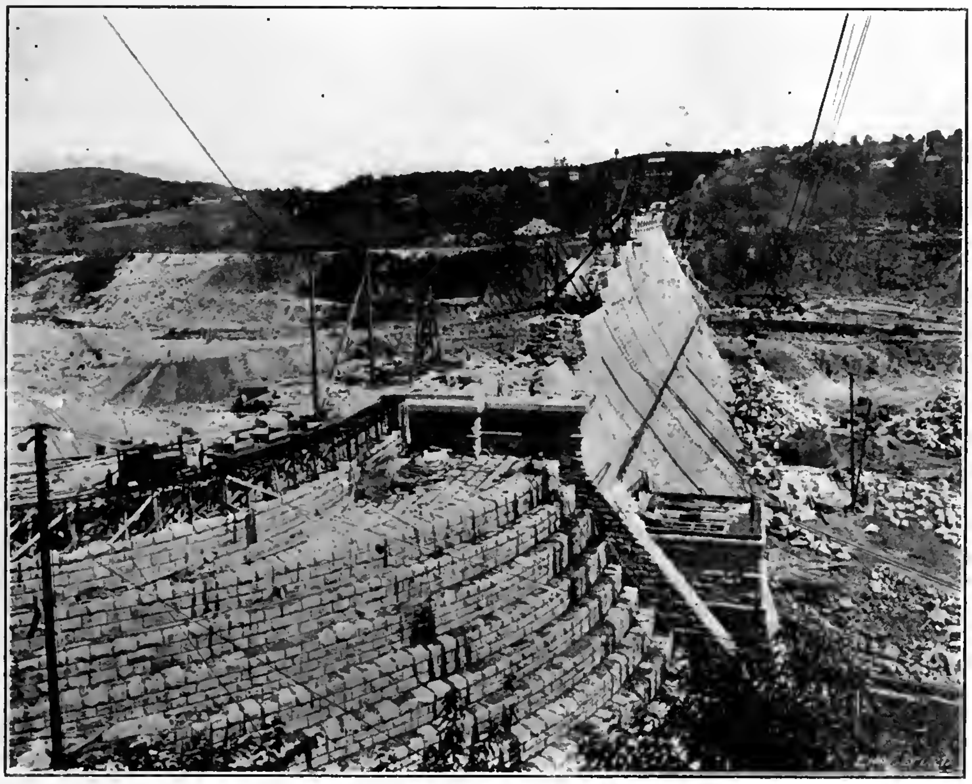
To facilitate digging, the bank is shattered with dynamite in advance of the steam shovel. A row of holes about 20 feet apart is made at the track level and another row about 30 feet above them: they are inclined slightly upwards from the horizontal and are 2 or 3 feet in diameter at the beginning, 6 inches at the end and are about 20 feet long. They are rapidly washed out by one man with a flexible 1-inch hose and 20 feet of 1-inch steel pipe having a 5/16-inch nozzle through which he plays a 300-pound hydraulic jet. The holes are ordinarily made in about 1½ hours each, and a 50-pound box of dynamite put in the end, and sand tamped in. Several holes are fired at once and shatter the bank so that the steam shovel can penetrate it easily, but they do not throw it down. A third row of holes is made in the surface of the ground parallel to the top of the bank and about 20 feet back from the edge. These are square pits, dug with shovel and pick to a depth of about 15 feet, charged, tamped and fired in the usual way.

Steam and water pipes are bracketed out from the curved downstream face of the dam, and ladders and scaffolds are suspended there for the masons to point the course joints. Access is had to the top of the dam from the hillsides at both ends and by stairways up the face to the gatehouse and by a diagonal line of stones which project a few inches in successive courses near the south end. All the derrick engines are furnished with steam from a 400 horse-power battery of boilers in a power house about 300 feet below the dam, from which the mains extend without jacketing about 500 feet in both directions to the opposite ends of the dam. The present consumption of coal is about 500 tons a month, including that used at the quarry and by the locomotives. The present force works one shift per day and includes about 100 stone cutters and masons and 500 other employes and laborers and 75 horses.

In the revised design of the dam the length of spillway is 1,000 feet; masonry dam, 1,000 feet; embankment and core wall, 300 feet; making a total length of 2,300 feet. Two hundred and fifty feet of spillway is at elevation 196 feet, and 750 feet is at elevation 200. The maximum flow line will not exceed elevation 206. The elevation of roadway on top of dam is 216 feet, and the lowest point of the foundation is 84 feet below the Croton datum, making the height 300 feet. The top of the dam is 166 feet above the bed of the Croton River, and the lowest point of the foundation is 134 feet below the bed.

The old Croton dam, which was constructed in the years 1837 to 1843, is located 3¼ miles above the new Croton dam. The reservoir back of it has an area of 498 acres and a capacity of 2,000,000,000 gallons. The elevation of the crest of this dam is 166.67 feet. The new Croton reservoir will encompass the old reservoir and have a capacity of 32,000,000,000 gallons. The total area of its watershed will be 373.32 square miles. The area of this new reservoir will be 3,425 acres, while its length (new Croton dam to Croton Falls) will be 19 2/3 miles. The Muscoot dam now building will form a dividing wall about midway of the reservoir.

The accompanying view looking north is made from a progress photograph taken July 23, 1902, and gives a specially good idea of the curved batter of the downstream face and its great height as compared with that of the man standing in the center of the foreground. The wing wall on the downstream side has been torn away at the left and the core wall has been demolished at the right, and the debris from this masonry is seen scattered in the foreground. It is being handled and removed by the boom derrick and the cableway, and the excavation is to be carried down there to solid rock for the foundations of the masonry extension. The steam shovel is at work south of the point of view at about the level of the foreground. In the background the gate chamber is seen at the left and a portion of the spillway masonry, curving upstream, at the right.



View Looking South, Showing Spillway and Gate Chamber.

The view looking south is at the same date and shows the north end of the masonry dam, its connection with the curved spillway and the gate chamber. The broad horizontal triangular surface of the spillway is not its top, but is the level directly below the bridge span of 200 feet on which the roadway is to be carried across the spillway to the north side of the valley. The buttress at the left of this level is the abutment pier which terminates in a beveled course for the skewbacks of the cut-stone arch which has been designed to form the bridge. On the upper part of the spillway a timber trestle has been terraced up on one of the offset steps for the material track on which a construction train is shown. The arrangement and operation of the traveling derricks on top of the dam masonry is seen, together with the successive steps in which the masonry is being completed. The 1,465-foot span cableway is seen parallel with and beyond the downstream face of the dam. The high curved bank in the background is where the steam shovel is excavating for the extension, and its spoil is dumped from the end of the bank on the left. The lines indistinctly seen across the downstream face of the dams are steam and water pipes, ladders and scaffolds which will be removed.

The revised estimate of total cost of the dam and auxiliary work is about $6,500,000, of which about $1,200,000 remains to be expended. Considerable work has been done in clearing and preparing the area to be submerged and in building new highways and several bridges are to be built, some of which are to have long spans and high abutments.

The dam was designed and its construction commenced under direction of Mr. Alphonse Fteley, past-president of the American Society of Civil Engineers. Mr. W. R. Hill is now chief engineer and Mr. Charles S. Gowan is division engineer in charge of construction. Messrs. Coleman, Breuchaud & Coleman are the contractors, and Mr. Jules Breuchaud of that firm directs the work. Mr. J. B. Goldsborough is the contractors' superintendent.

The Electrolysis of Iron Pipes in and around Boston has led the Metropolitan Water and Sewerage Board to advocate the use of the double trolley system by the electric railways.

A Silent Water Heater, so called, an apparatus designed by Messrs. Nachtigall and Jacoby for heating a body of water by steam, is described in the "Practische Maschinen Constructeur." It consists of two disks enclosing an annular space, the whole submerged in the water. Steam is admitted by means of a pipe into the center of the device and issues into the annular space through an opening extending entirely around the periphery of the steam space. The upper and lower walls of the annular chamber are pierced by a number of holes through which the water to be heated is drawn by a sort of suction action by the steam issuing from the peripheral opening. The water coming in contact with the steam, condenses it, becomes warmed and flows at increased velocity in the direction of the steam, escaping into the main body of the water through a peripheral opening between the disks, which lack meeting at the edges by the amount of the opening. The apparatus is, in brief, a special form of jet condenser, of small dimensions, designed to heat water without noise.

The Water Supply of the Michigan Asylum for the Insane at Kalamazoo.

By Geo. S. Pierson, M. Am. Soc. C. E.

The Asylum for the Insane at Kalamazoo is situated upon a plateau lying at an elevation of about 170 feet above the level of the Kalamazoo River, and about 140 feet above the general level of the city of Kalamazoo. It lies so high above the general level of the city that it cannot well be supplied with water from the city water-works. There are about 1,500 to 2,000 persons at the Asylum and there is required for normal use about 250,000 gallons of water per day. A much larger quantity should, of course, be available for fire protection.

About 30 years ago an open well was constructed in a ravine near the Asylum buildings, which lies about 100 feet below the general level of the grounds on which the principal buildings stand. This well consists of a brick curb resting upon a wooden shoe. A pumping station was established at this well, and the water forced to the Asylum grounds and buildings. Although never productive, this well furnished sufficient water for the ordinary requirements of the Asylum for some 10 or 15 years.

When the increased demands of the Asylum and the decreased production of the well combined to make the supply inadequate, tubular wells were driven in an area extending some 700 or 800 feet up the valley from the well, and these were connected into a common pipe line and discharged into the well to supplement its supply. These wells were generally from 80 to 100 feet deep, and when first put down they yielded a fair amount of water. Owing to some peculiarity in the stratum in which the well screens lay, however, the screens soon corroded so as to prevent almost entirely the flow of water of the driven wells. This corrosion was so rapid that within a couple of years the driven wells would practically cease to produce. As these wells became inoperative from this cause, others were put down with like results. After a few years of this procedure it became apparent that no permanent supply could be maintained in this manner except at a very great cost.

At about this time a water tower was constructed so as to afford better fire protection and help out the limited water supply by its storage capacity. This water tower consisted of an iron tank having a capacity of about 250,000 gallons, and the bottom of the tank rested on brick masonry 100 feet high above the general level of the ground upon which the Asylum buildings stand.

After a few years more the increased demands and failing supply combined to produce a shortage of water even when the pumps were run continuously and advantage taken of the storage of water during the hours of least consumption.

It had been clearly demonstrated that no adequate supply could be obtained by driven wells without putting down a new series of wells each year or two at a considerable yearly expense. This is a peculiarity of certain strata which has been observed in numerous instances in some sections of lower Michigan. It is not generally true of strata which lie nearer the surface.

At about the time the standpipe was erected at the Asylum grounds, the entire power plant of the institution was reconstructed. A large central steam and power plant was installed which furnished steam for heating, electric current for lighting and electric power for various purposes. At this time, two new 500,000-gallon geared pumps were installed at the pumping plant near the old open well, operated by electric power.

No surface water supply could well be brought within reach of this new pumping station. It was therefore necessary to deliver an adequate supply within reach of the present pumping station from ground waters or to abandon the pumping station.

Investigations were therefore made of the strata over an area extending some 1,500 feet up the valley from the old open well, by sinking test wells at various points and taking out samples of earth at each foot or so in depth as the wells were driven. Previous experience with wells in this area had indicated that the only available water-bearing strata probably lay within 50 feet of the surface or at a depth of about 80 to 100 feet. As these investigations had reference more particularly to the feasibility of procuring a supply by an open well, the test wells were generally sunk to a depth of about 50 feet, at which point they usually entered clay. No regular and sharply defined stratification was revealed by the test wells. Generally, however, at a depth of 30 to 40 feet, fairly coarse material was found. The appearance of this was not as favorable to the passage of large quantities of water as might be desired, but owing to the difficulties which had been met in securing an adequate supply by any other means, it was determined to sink an open curb at a point where the conditions seemed most favorable. After this point was selected, additional test wells were sunk and samples taken at three points equidistant from each other in the circumference of the proposed curb.

The plan of the well is shown in the illustrations. The well was built in the following manner: An excavation was first made to the water line. A heavy 6x6-inch iron angle was assembled in the bottom of the excavation, and upon this was erected a steel shell 25 feet high and 25 feet in diameter at the shoe. This shell was lined with a brick wall laid in Portland cement mortar. The brick wall rested upon the iron angle and was anchored to the iron shell at frequent intervals by anchor irons bolted to the shell and extending nearly through the brick work. The curb was built intact above the water line and the masonry allowed to set before any attempt was made to sink it.

Upon the top of the curb was bolted a ring formed of heavy oak planks and upon this was fastened a curved iron T-rail, which served as a track on which a dredge platform revolved. The dredge was operated entirely by hand. It consisted of a framework of timbers supported entirely by an axle which lay on two beams crossing the dredge platform and by a windlass and ropes fastened to the lower end of the dredge frame. The dredge could be raised or lowered slightly by raising the bearings on which the axle rested and could be swung from the shoe of the curb to the center by operating the windlass. It was a plain bucket dredge constructed of link chains and steel buckets, and was of such a length as ordinarily to reach a trifle below the shoe. The dredge was operated by four men, two on each crank, working at short shifts. During the operation of the dredge it was continually revolved about the circular track.

During the sinking of the curb there was no motion of any kind perceptible to the eye. By revolving the dredge so as to keep it working at the points where the curb was highest it could be kept almost precisely level; probably at no time during the process of sinking was the curb more than 3 or 4 inches out of level. The rate of sinking was a little less than one foot per day. No attempt was made to keep the water out of the curb during the process of sinking, and, during the latter part of this process, the water stood three feet higher inside the curb than outside. The dredge buckets were perforated so as to prevent the reduction of the water level inside the curb and thus maintain an increased pressure within the curb in order to prevent the inflow of sand under the shoe. With the exception of one or two men the labor was performed entirely by Asylum patients, Mr. Turnbull, the engineer at the Asylum, being in direct charge of the work.

The stratum at the point where the shoe finally rested was composed of gravel intermingled with some sand of varying degrees of

View of the Kalamazoo Asylum Well during Process of Sinking.

fineness. This was excavated as deeply below the shoe as possible, and considerably deeper at the center than near the shoe. The bottom was then covered with coarse screened gravel, then a layer of still coarser screened gravel and small stones, and finally with a layer of cobblestones.

As a protection against evil disposed or irresponsible persons, the well is lighted entirely by a skylight surrounding the finial, no openings being left in the wall.

The new well is 900 feet from the old well at which the pumping station is located. The two are connected by a siphon. It would have been very desirable to lay the siphon continually ascending from the new well to the old, as at this point a small air pump could readily have been installed to keep the siphon free of air. The static level of the water in the new well is a number of feet above the static level of the water in the old well, however, and it was not practical to do this. The siphon is, therefore, laid continually descending from the new well to the old and the air in the siphon collects in the air chamber in the new well shown in Fig. 2.

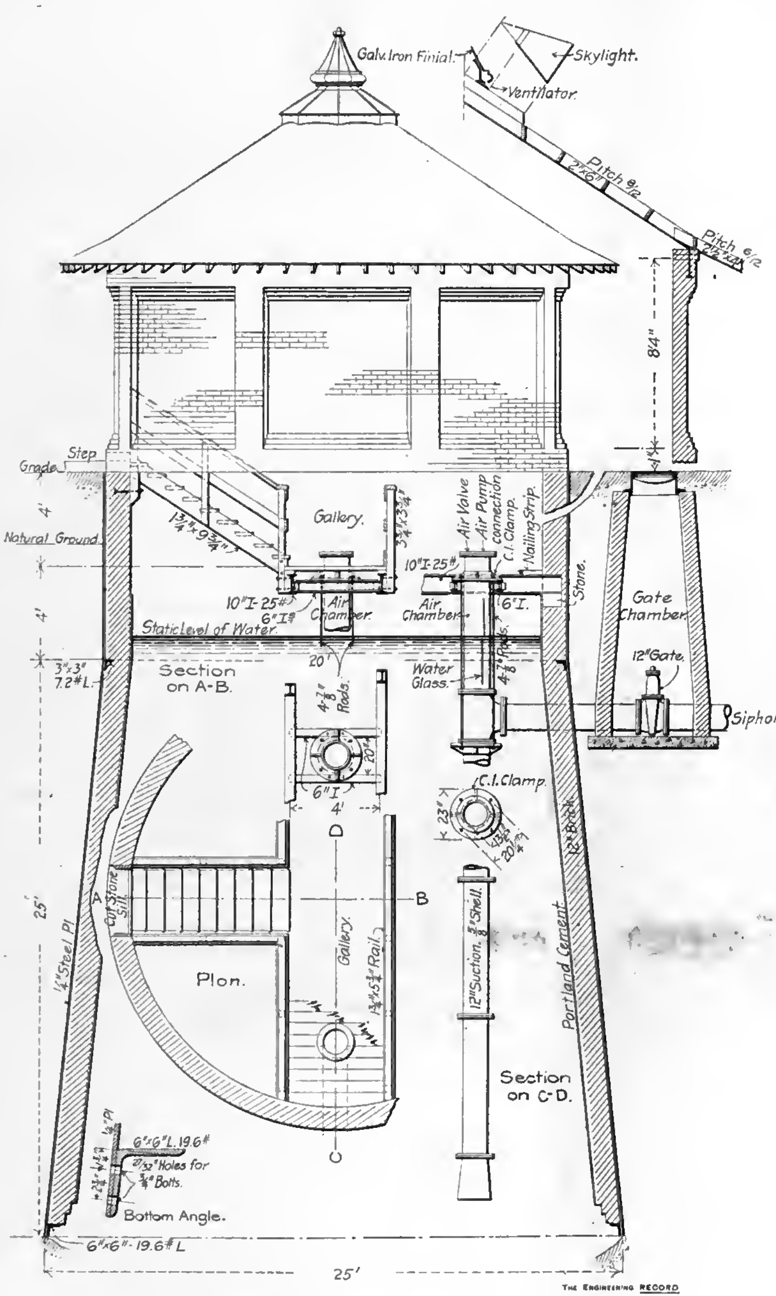
The pumps at the pumping station are operated intermittently, usually for three or four hours in the morning only. When the pumps are idle the level of the water in the new well rises to approximately the point shown in the figure, and forces the air out of the air chamber through a small air valve which operates automatically by gravity. At the same time an automatic valve and float closes the lower end of the siphon where it discharges into the old well, as pumping is suspended and the water level in the old well rises. This is to prevent the continued overflow from the new well into the old and the backflow of water into the ground from the old well, as well as to allow the water in the new well to rise to as high a point as possible for the purpose of relieving the siphon of air, as already described.

There appeared to be some doubt as to whether this method of exhausting the siphon of air would be adequate, especially with continued use and when large quantities of water were being drawn, and an air pump connection was therefore placed in the head of the air chamber for use in case the previously described method should prove inadequate. Up to the present time, however, it has proved entirely adequate and the operation of the two wells simultaneously has been entirely automatic, and, as the engineer says, "I used to go up there once in a while and look at the gauges, but they have always been all right, and I don't go there at all now." There are glass water columns on the air chamber, so that it can readily be seen by inspection whether or not any air is in the siphon line.

In the lower end of the siphon line is set a branch which is connected directly to the suction line of the pumps so that the pumps may draw exclusively from the new well, using the siphon line merely as a suction line if it is desired to do so, which is quite improbable.

Approximate tests of the capacity of the new well indicate that it will furnish about 1,000,000 gallons a day.

The method of increasing the water supply at a point where a pumping station is already established which has been described, has been used by the writer in other cases. Fifteen years ago a plant similar in the essential details was constructed by him on a considerably larger scale, the siphon being 24 inches in diameter and 2,900 feet long. This siphon has a lift of 20 to 25 feet and has been in operation without interruption for the past fifteen years.



Details of the New Well at Kalamazoo.

Another Tunnel under the Thames at London has just been completed after three years' work. It is for workmen who cross between Millwall and Greenwich, and is 1,217 feet long and 11 feet in diameter. It is 60 feet below the high-water level and its crown is 13 feet below the river bottom. It was driven under air pressure by a shield started from the north side. The entrance at either end is a shaft 35 feet in diameter with stairways and an electric elevator. The contractors were J. Cockrane & Sons, and the cost was $600,000.

The Marine Water-Tube Boiler is referred to as follows in a report of the British Admiralty committee appointed to consider certain questions concerning marine boilers: "In the course of their investigations the committee have watched the Babcock & Wilcox boilers fitted in the S. S. "Martello" of the Wilcox Line, employed in the Atlantic trade between Hull, Boston and New York, and copies of the reports of their inspections have from time to time been forwarded to their Lordships. These inspections have taken place at the end of every round voyage for 14 months, and the committee's opinion is that these boilers have stood the test of usage in the mercantile marine extremely well. The vessel has run about 91,000 miles since the boilers were put in, and has usually been less than a week in port at either end; the only repairs required have been those of the ordinary upkeep of any boiler, such as fire-bars, brickwork, etc., and only six tubes have required renewal. This opinion is strengthened by the inspection of boilers of the same type fitted in the "Numidian," the "Buenos Ayres," and the "Turret Cape." In the case of the last named vessels, the boilers have been in use seven years, and cannot have been as well looked after as they would have been in the Navy, and their condition when examined recently was satisfactory. The committee have also examined and tested boilers of the same type in H. M. S. "Sheldrake," and find that, although they have been in use for four years, their condition is good and they have given little trouble. From the information which has been brought to the notice of the committee, it appears that water-tube boilers are being very little used in large ships belonging to the mercantile marine, and that their use in such ships is increasing very slowly. In the British mercantile marine, the only type of water-tube boiler installed in ocean going vessels is the Babcock & Wilcox, in some ships of the Wilson and the Petersen-Tate Lines, and in three ships of the Allan Line; in these last, however, only one water-tube boiler is fitted in each vessel to assist the original cylindrical boilers. In the United States mercantile marine, Babcock & Wilcox boilers are used to a small extent, principally in the ships plying on the Great Lakes, and in the American Navy many Babcock & Wilcox boilers are in use."

Two Recent Water-Power Plants on the Arve River, France.

Two water-power plants have recently been developed on the Arve River in France to furnish power for an electric railway running from Fayet to Chamonix, this road now giving tourists direct communication by railway between Geneva and the picturesque valley at Chamonix. In general the plants comprise waterways tunneled in the rock, as is characteristic of many of the water-power plants in these mountainous regions of Europe. In both plants enlargements are provided in the waterways to allow for the deposition of sand and gravel, one of the decantation chambers, as they are called, being subterranean. In the electrical end of the work an unusual method of regulation has been resorted to. A description of the railway as well as of the power plants is given in two recent issues of "Le Genie Civil."

The road has a total length of 11.8 miles and contains two heavy grades, one of 9 feet in 100 in a length of 7,070 feet, and the other of 8 feet in 100 in a length of 4,547 feet. The elevation of Fayet is 1,904 feet; that of Chamonix, 3,404 feet. One of the power plants is located 3.1 miles distant from Fayet near Servoz, and the other 5 miles distant near Chavants.

The Servoz works utilizes the upper 128 feet of a 584-foot fall, of which an electro-chemical establishment at Chedde uses the remaining 456 feet. A diversion of the River Arve has been designed to obtain a delivery of 423.6 cubic feet of water per second, so that 4,500 horse-power measured on the turbine shafts can be realized in summer. During winter, the discharge of the river drops to 211.8 cubic feet per second, so that the water power can only furnish the turbines with 2,250 horse-power. The corresponding section of the road, however, only required, according to estimate, 1,380 horse-power, and the road is not operated during winter, that is, at times of low water. The water, which is impounded by means of a dam, is admitted into a tunnel of large cross-section, to provide for sedimentation, then passes through a second tunnel to a covered forebay from which are taken four penstocks, 3.28 feet in diameter, leading to the power house. A double needle dam, which permits the passage of sand and gravel, has been built, a former dam of stop planks having been carried away by high waters. The intake to the first tunnel is guarded by two grills of flat iron, 2.75x0.31 inches, with 0.95-inch spaces for one and 0.78-inch spaces for the other. The delivery into the tunnel is regulated by means of three gates, 7.1 feet wide, placed immediately behind the grills.

The first tunnel or decantation chamber is 755 feet long and has a constant cross-section, the water having a width at the entrance into the tunnel of 20.67 feet and a depth of 8.85 feet, and at the extremity, a width of 15.75 feet and a depth of 11.8 feet. The wet section being about 183 square feet, the resulting velocity with 282.4 cubic feet flow per second is 1.54 feet per second, which is considered sufficiently slow to allow for sedimentation. In continuation of the chamber there is an emptying canal by which the chamber is cleared of the accumulated deposits, this work being done every week, for about five hours, during which time the operation of the works has to be interrupted. The second tunnel is 1,640 feet long and has a capacity of discharging 423.6 cubic feet of water per second at a velocity of 7.87 feet. The second tunnel empties into a water chamber from which a branch is taken to the forebay for the Servoz works and another for the Chedde works.

The power house contains four turbines of 320 horse-power each, operating at full load at 460 revolutions per minute and two 60-horse-power turbines making 520 turns per minute. The turbines are mounted on horizontal shafts and are direct connected to the generators. The turbines are fitted with draft tubes and the tail water is carried away to the Chedde works. The generators are 6-pole direct-current dynamos arranged for partial separate excitation, the method of regulating the machines being very interesting. The main turbines are not provided with any regulation and cannot therefore maintain a constant speed. At no load, their speed is 615 revolutions per minute, and when developing 340 horse-power, 448 turns. The fields of the dynamos carry two windings, one passing a determined fraction of the total dynamo current and the other the current from the separate exciting dynamo. At no load, the field excitation is produced only by the practically constant current from the independent dynamo and is regulated to give at no load speed 550 volts. When a train enters upon the section of the road supplied by the works, the turbines slacken up in accordance with the load and the dynamos turn more slowly; but their excitation is reinforced by the current which they set up and the reinforcement will be greater the more the reduction in speed. The scheme is that speed changes are compensated by variations of the excitation and a pressure has been obtained constant within 5 per cent., from 570 volts at no load to 540 volts at 440 amperes. The normal working of the dynamos is 370 amperes. The exciter turbines are controlled by regulators, and the exciter dynamos are of 40 kilowatts capacity at 120 volts.

The Chavants works utilizes a fall of 308 feet in which during the favorable season, a discharge of 406 cubic feet per second is available, corresponding to 10,650 horse-power on the turbine shafts. The water is diverted for this water-power development by means of a dam 9.84 feet high, curved upstream. From the intake the water is first passed through a tunnel 3,585 feet long, then through a decantation or settling chamber and finally through a second tunnel 3,460 feet long. Both tunnels, which pass through a more or less compact rock, are 8.2 feet wide and 9.84 feet high. Their entrances are protected by grills. The settling chamber is open, located in a depression of earth, and has a length of 403.5 feet and a width of 32.8 feet. The bottom of the chamber has an inclination of 1 in 100 in the direction of its length and also a transverse pitch of 1 in 10, in order to concentrate the deposits toward one of the walls of the chamber to facilitate their removal. The velocity of flow in this chamber does not exceed 1.9 feet per second and it takes about 3½ minutes for the water to pass through the chamber. It is cleared as in the other works, during interruptions of the service.

At the extremity of the second tunnel the water is delivered into an open forebay, which has a width of 18 feet. Its length is only 11.15 feet, but it is arranged for increase with enlargement of the plant. At the forebay an overflow is provided for the disposal of excess water, designed to take the maximum flow of water. From the forebay the water is led in two penstocks each supplying a pair of turbines. The penstocks are built in sections each 21.3 feet long and 2.62 feet in diameter, of boiler steel. The thickness of the plates varies from 0.23 inch at the forebay to 0.43 inch at the bottom near the power house.

The generating units consist of four horizontal 320-horse-power turbines directly connected to six-pole 200-kilowatt dynamos and two 60-horse-power turbines driving two 40-kilowatt dynamos for exciting purposes and local lighting. Ordinarily, one of the exciter units is in reserve and the road service requires three of the four generators. The same system of regulation has been applied to the Chavants works. When the dynamos operate at no load, their speed is 600 revolutions per minute and the tension 550 volts. The speed falls to 450 turns and the tension rises to 680 volts when the load reaches 290 amperes. The high voltage is to compensate for the losses in the feeders, which in this case are quite long.

Tests of Special Properties of Mortar.

In connection with the construction of the Wachusett dam, the Metropolitan Water and Sewerage Board has been conducting a series of continuous tests of cement which have now lasted for over five years for some brands. The results are summarized in the report for 1901 of the chief engineer, Mr. F. P. Stearns, who also gives the following notes concerning some special investigations:

In view of the very large amount of mortar to be used in the dam and the importance of having it as water-tight and strong as possible, extensive experiments were begun early in 1901, to determine the permeability and strength of mortars made of the natural and Portland cements which were to be used in the construction of the dam, mixed with different proportions of coarse and fine sands.

The experiments on permeability were made by placing the mortar in cast-iron cylinders, 22 inches long and about 6 inches in diameter. After the mortar had set, caps were bolted to the tops of the cylinders and water was admitted to the cylinders between the caps and the mortar with a pressure of 74 pounds to the square inch. There were 144 cylinders used in the experiments, and the apparatus was so arranged that the water pressure could be applied to 24 cylinders at a time. The applied water was first filtered through sand, to remove all suspended matter.

There were 1,494 briquettes made and broken, to determine the tensile strength of the mortars. It was found that the use of a sand with a very large proportion of coarse particles and a much smaller percentage of the finer grades makes a mortar both less permeable and stronger than where a larger proportion of the finer grades is used, provided the proportion of sand to cement does not exceed 3 to 1.

In addition to the experiments upon permeability and strength of mortars, other experiments were made to determine the relative strength of mortars used immediately after wetting and mixing, and when used at different intervals up to two hours after they are first wet and mixed. These experiments were very extended, as they were made with mortar mixed with different grades of sand, with Portland and natural cement, with slow-setting and quick-setting cement, and with mortar that was worked continuously from the time of mixing until it was put into the molds, and also with mortar which was not worked after it was mixed until just before it was put into the molds. The briquettes were broken at the end of fourteen days, twenty-eight days, and three months after mixing.

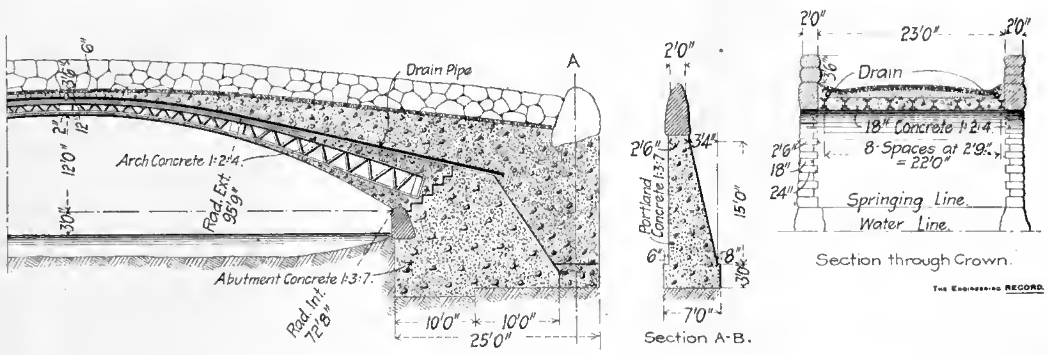
It was found that when the cements, both Portland and natural, were so manufactured as to take the initial set slowly, the strength of the mortar was not diminished by a delay of two hours in putting it into the molds; and when the mortar was worked continuously to the time of filling the molds, there was an increase in strength occasioned by the delay. When the cements were so manufactured as to take the initial set quickly, the results obtained with the quick-setting Portland cement were not materially different from those obtained with the slow-setting cement, except that when the mortar was not worked there was a slight loss of strength in the briquettes molded at the end of one and a half and two hours, and at no time was there much gain in strength occasioned by delay in filling the molds. The results obtained with the quick-setting natural cement were less favorable, as the briquettes broken at the end of fourteen days showed a great loss of strength when there was much delay in molding the briquettes. At the end of three months, however, the briquettes made with mortar which had been worked continuously from the time of mixing showed slightly greater strength than that put into the molds immediately, and the loss of strength of the mortar not worked was not very marked except for the 1½ and 2 hour periods.

The Cost of Pumping for the Metropolitan Water system of Boston during 1901 was $2.52 per million gallons pumped, as compared with $9.64 in 1897. A saving of $0.82 per million gallons was effected over the cost during 1900, this reduction being brought about by the discontinuance of the smaller stations and by the introduction of more economical machinery and methods at the few large stations. The 1901 report of the Metropolitan Water and Sewerage Board states that the total quantity of water pumped during the year was 40,018,920,000 gallons.

The Manifold Power Systems of the Edison Electric Company, of Los Angeles, Cal., will be an interesting combination of electric works when completed. In addition to its present station, there is a hydraulic plant nearly finished in Mill Creek Canyon near Redlands, which has a canal capacity of 1,100 miner's inches, an effective head of 1,935 feet and machinery of 4,000 horse-power. On the Kern River 110 miles from Los Angeles, a dam will be built to divert 300 second-feet into a canal leading to a 20,000-horse-power station. There will be at least two three-wire transmission lines and the voltage will probably be around 60,000. At Los Angeles there will be an 18,000-horse-power receiving station. It is also proposed to build at once a new steam plant in the city to work in connection with the company's several hydraulic plants. It will have an ultimate capacity of 5,000 kilowatts in four or five units, the first installation to be 2,000 kilowatts. Water-tube boilers with economizers and superheaters will be employed, with oil-burning furnaces. It has not yet been decided whether direct-connected condensing engines or steam turbines will be used. Surface condensers will be installed, and a large traveling crane will span the engine room. The management of the company's affairs is in the hands of the president, Mr. John B. Miller, who supplied the above information.

The Rock Creek Concrete-Steel Arch, Washington.

Although the people of Washington have been disappointed by Congressional delay in pushing work on the concrete-steel Memorial bridge designed by Prof. W. H. Burr, an attractive structure of this sort on a much smaller scale has recently been constructed over Rock Creek in the National Park. Its general design and appearance are well shown in the accompanying illustrations. It is a segmental arch of 80 feet span and 15 feet rise and carries a 23-foot roadway; the clear width between the parapets is 23 feet and the width over all is 27 feet. The locality where the structure stands made it desirable to build a boulder bridge, if possible, for aesthetic reasons, but as only $17,500 was available for the purpose it was necessary to adopt some less expensive type of construction, that selected being a Melan concrete-steel arch with a boulder facing, the concrete of the soffit being darkened strongly by lampblack to harmonize with the face of the stones.



Half Longitudinal Section showing Parapet and Wing Walls.

The proportions of the concrete used in the several parts of the bridge are stated on the drawings. The boulders measure from about one-fifth cubic foot upward in size and were required to be "loose rock which shall be hard, sound, durable and of a quality to be approved by the Engineer, whose edges have become weathered or water-worn, or both, and are more or less rounded. The boulder face of each stone shall project at least 2 inches beyond the neat lines of the bridge, and this projection shall not exceed 15 inches, nor shall it be greater than one-half the least horizontal dimension of the stone. All joints shall be scraped and brushed clean of mortar to the depth indicated by the Engineer. The mortar shall consist of 1 part Portland cement and 2 parts sand. The backs of all boulders shall be plastered with a layer of mortar as specified, at least one-quarter inch thick, immediately before ramming the concrete against them." No serious trouble was experienced in securing the boulders.

The arch stones are from 3 to 4 feet deep, 1½ to 3 feet wide and 1½ to 2 feet long, all dimensions being exclusive of the projections beyond the neat lines. The joints were dressed so as not to exceed 1½ inches at any point for at least two-thirds their depth and two-thirds their length, and were roughly pointed. Each stone was attached to the top of the adjacent steel girder by a ¾x¼-inch steel cramp cemented for at least 2 inches in a hole in the stone. The outside girders were bound together, just before the concrete was put about them, by means of four ¾-inch wire ropes. A number of arch stones were made by splitting boulders into two pieces, the fresh face of each being turned toward the girder.

The requirements for the abutments, spandrels and wing-walls stated that no dressing would be required on the stones for such parts, for which only well-shaped boulders, laid on their broadest bed, were allowed. Dressing was permitted, however, if the stones could not be bedded properly without it, and, as a matter of fact, was necessary in most cases. The parapet contained a number of through stones, and these were used exclusively for its top.

A CONCRETE-STEEL BRIDGE OVER ROCK CREEK, WASHINGTON, D. C.

The effect of the structure is striking, and it is greatly admired. It was designed a year ago under the supervision of Capt. Lansing H. Beach, Engineer Commissioner of the District at the time, and built under his direction and that of Col. John Biddle, his successor, assisted by Capt. H. C. Newcomer; Mr. W. J. Douglas is the engineer of bridges of the department. The contract was placed with Messrs. Talty & Allen, of Washington, at $14,890, exclusive of steel and royalties, and the total cost, including inspection, was $17,500.

A Solid-Floor Single-Track Plate-Girder Bridge.

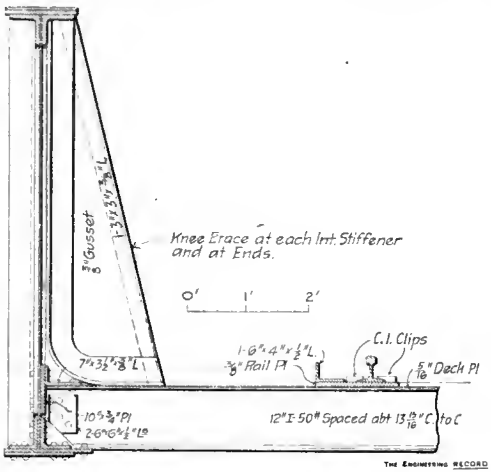
Bridge No. 421½ of the Lake Erie & Western Railroad is a single track through plate girder of 75 feet span out to out, with abutments skewed 37 degrees 10 minutes to the bridge axis and the track on a 2-degree horizontal curve. The girders are 15½ feet apart on centers and have rounded upper corners. The webs are 7 feet deep, shop spliced in three sections and stiffened by pairs of 5x3½-inch vertical angles and fillers from about 7 to 10 feet apart. The flanges are of the ordinary T-shaped section made with pairs of 6x6x¾-inch angles and pairs of 14x¾-inch cover plates. The bed plates at both ends have ¼-inch sheet lead packing on the masonry and at one end there are ten 2-inch rollers under each girder. The girders are sway-braced by solid gusset plates reaching from the top flange to the solid floor and riveted to the inside vertical web stiffener angles, which are curved at right angles at the bottom and form continuous connections which are riveted to the top flanges of the floorbeams.

The span is proportioned for a dead load of 1,700 pounds per lineal foot, a live load of two 100-ton consolidated locomotives followed by 3,000 pounds train load per lineal foot and an impact of 15 per cent. for the girder and of 25 per cent. for the floor. These produce a maximum moment of 2,007,300 pounds in the flanges and an end shear of 124,700 pounds.

The bridge floor is carried on 12-inch 50-pound I-beams about 14 inches apart, which, at each end, have pairs of vertical angle clips shop-riveted to their webs and field-riveted to a 10x¾-inch continuous reinforcement plate riveted to the girder web just above the edge of the flange angle, as shown in the detail cross-section. The lower corner of the floorbeam is cut off at 45 degrees to clear the bottom flange angle, but is left long enough to engage the upper side of a special 17½x⅝-inch flange plate which is riveted to the bottom side of the flange angles above the regular 14-inch cover plate and projects about 3½ inches to take one row of rivets in the floorbeam flanges.

The entire upper surface of the floorbeams is covered with flat 5/16-inch steel deck plates extending from girder to girder and from end to end of the span. These plates are riveted to the top flanges of the floorbeams and their edges are secured by the wide flange of a 7x3½-inch horizontal angle field-riveted to them and to the web on the girder, so as to form a finish and a stiffening to the floor. Each floorbeam has a moment of 504,000 pounds and an end shear of 9,500 pounds, which is taken by the four double-shear rivets through its web and the eight single-shear rivets through the web of the girder. The lower flange of the floorbeam is kept 1/16 inch above the top of the 17½-inch flange plates to prevent the latter from receiving any bearing load. The rails are secured by cast steel clips and are seated on ⅜-inch bearing plates 16¼ inches long above every floorbeam. These plates are alternately 6 and 10 inches wide and receive also the 6x4x½-inch guard angles. This arrangement permits the track to be located at pleasure between the girders, affords a stiff and watertight floor and occupies remarkably little vertical space, the base of rail being only 14 9/16 inches above the bottoms of the rivet heads in the lowest part of the girder.

On account of the great skew, one girder projects about 21 feet beyond the end of the other at each abutment, and for this distance the floorbeams, which are riveted to the long girder, require special supports at their other ends. This is afforded by riveting them to the webs of special 12½-inch plate girders seated on and anchored to the abutment masonry. The shore edge of the deckplate is parallel with the face of the abutment from the end of each girder nearly to its intersection with the track where, on the side nearest the long girder, it makes an angle of 127 degrees and 10 minutes, crosses the track at right angles, makes a right angle and follows parallel and close to the guard rail for about 9 feet, and then intersects the edge which is parallel with the face of the abutment at an angle of 142 degrees and 50 minutes. This brings the floor square with the track at the end of the bridge and parallel with the abutment each side of the track. An abutment wall follows the angles of the end of the floor and carries the girders under each of the intersecting sides above described. The girder parallel to the track is supported at both ends and in the middle and has flanges made of single 5x3½-inch angles. The oblique girders are web-connected by oblique vertical angle-plates, with the webs of the longitudinal and



Section through Solid Plate Floor.

transverse girders and with the ends of the main span girders.

This bridge was designed and built by the King Bridge Company in accordance with the requirements of the engineering department of the Lake Erie & Western Railroad Company.

A Plan of the Venetian Campanile, drawn by Mr. W. Hilton Nash in 1875 from measurements he made, has been published by the "Builder." It gives the outer wall as measuring about 37 feet on a side and 4 feet thick. The inner wall was 3 feet 9 inches from it and 3 feet 9 inches thick. He states in a note accompanying the sketch that there were serious cracks in the structure which he attributed to unequal pressures caused by the decay of the timbers bonding the two walls together.

The Comprehensive Study of the Quality of Water has been undertaken by the Division of Hydrography of the U. S. Geological Survey, with the corporation of laboratories in different parts of the country. The division has been carrying on investigations of the quantity of water available in the various States, which have already proved of much value in projects for power development. The examination of the quality of the water will increase the usefulness of these investigations by supplying information desirable in estimating the availability of streams as sources of supply for potable or manufacturing purposes, and for this reason the new venture is to be commended. In order to secure uniformity in the work, Dr. F. H. Newell, who is in charge, has issued a circular advising the adoption of the analytical methods recommended by the special committee of the American Public Health Association, already given in detail in this journal.

The Mechanical and Electric Equipment of the Pittsburg & Lake Erie R. R. Terminal, Pittsburg.—II.

In the issue of The Engineering Record of August 2 the mechanical plant of the Pittsburg terminal station of the Pittsburg & Lake Erie Railroad was described at some length, making it necessary to defer to the present issue the account of the heating and ventilating system which has been provided. As explained in the preceding article, the terminal includes a seven-story headhouse with the station proper on the first floor and the general offices of the road on the floor above. The building contains many finely decorated rooms, and being located in a very smoky section of Pittsburg, a special effort was made to keep the interior clean. A greater part of the window sash is stationary, the balance being fitted with hinges and locks and all joints of all windows carefully packed with felt to prevent the leakage of air from the outside. A very elaborate system of ventilation was accordingly installed, involving the use of seven fans, by means of which a plenum is maintained in the building, to insure that very little air enters except through the designed channels.

The building is warmed by hot water, the direct system being employed in warming offices, with indirect radiation for the waiting and other public rooms. The offices, however, are also supplied with fresh air, but this is tempered and intended for ventilation only. The air circulating system is supplied with three blowers in the basement of the station building, the fans receiving fresh air through air shafts dropping from intakes above the roof. All the air is washed by water and tempered. By one fan it is then delivered through supplementary heaters and thence into the waiting room and adjoining spaces, all of which are, as stated, warmed by the air supply; by the other two fans it is discharged to tempered air shafts which rise through the building to distributing systems in each story for the ventilation of the offices. The exhaust of the air is effected by means of disk fans, one in the basement drawing air from the waiting room and three on the roof, two for the general office systems and the third for the toilet rooms, which is discharged independently into the atmosphere. Provision has been made for an internal circulation of the air in the offices during periods of unoccupancy, as on holidays and Sundays, by dampers, which close off the fresh air inlets and allow the practically unvitiated air rising through vent shafts to reach the intake shaft and pass downward to the basement to be recirculated. In this case the two roof exhaust fans belonging to the office system are shut down and the two blowers corresponding need only be run at a slower speed.

The methods and apparatus for the distribution of air can probably be understood from the basement, ground-floor and sixth-story plans, which are reproduced in accompanying drawings. For the passage of ducts, suspended ceilings over the corridors are resorted to, as indicated in the sixth-story plan, resulting in the concealment of the duct work. In the basement there has been a close utilization of space, the building resting on made ground and bringing heavy latticed girders of the foundation in the basement story. All the fresh air is received through two intake shafts, each of which delivers to a room in the basement where the tempering and washing apparatus is installed. In each case, the water-spray method of dirt elimination is employed and the cold air is first warmed slightly so as to prevent any freezing in the washing apparatus.

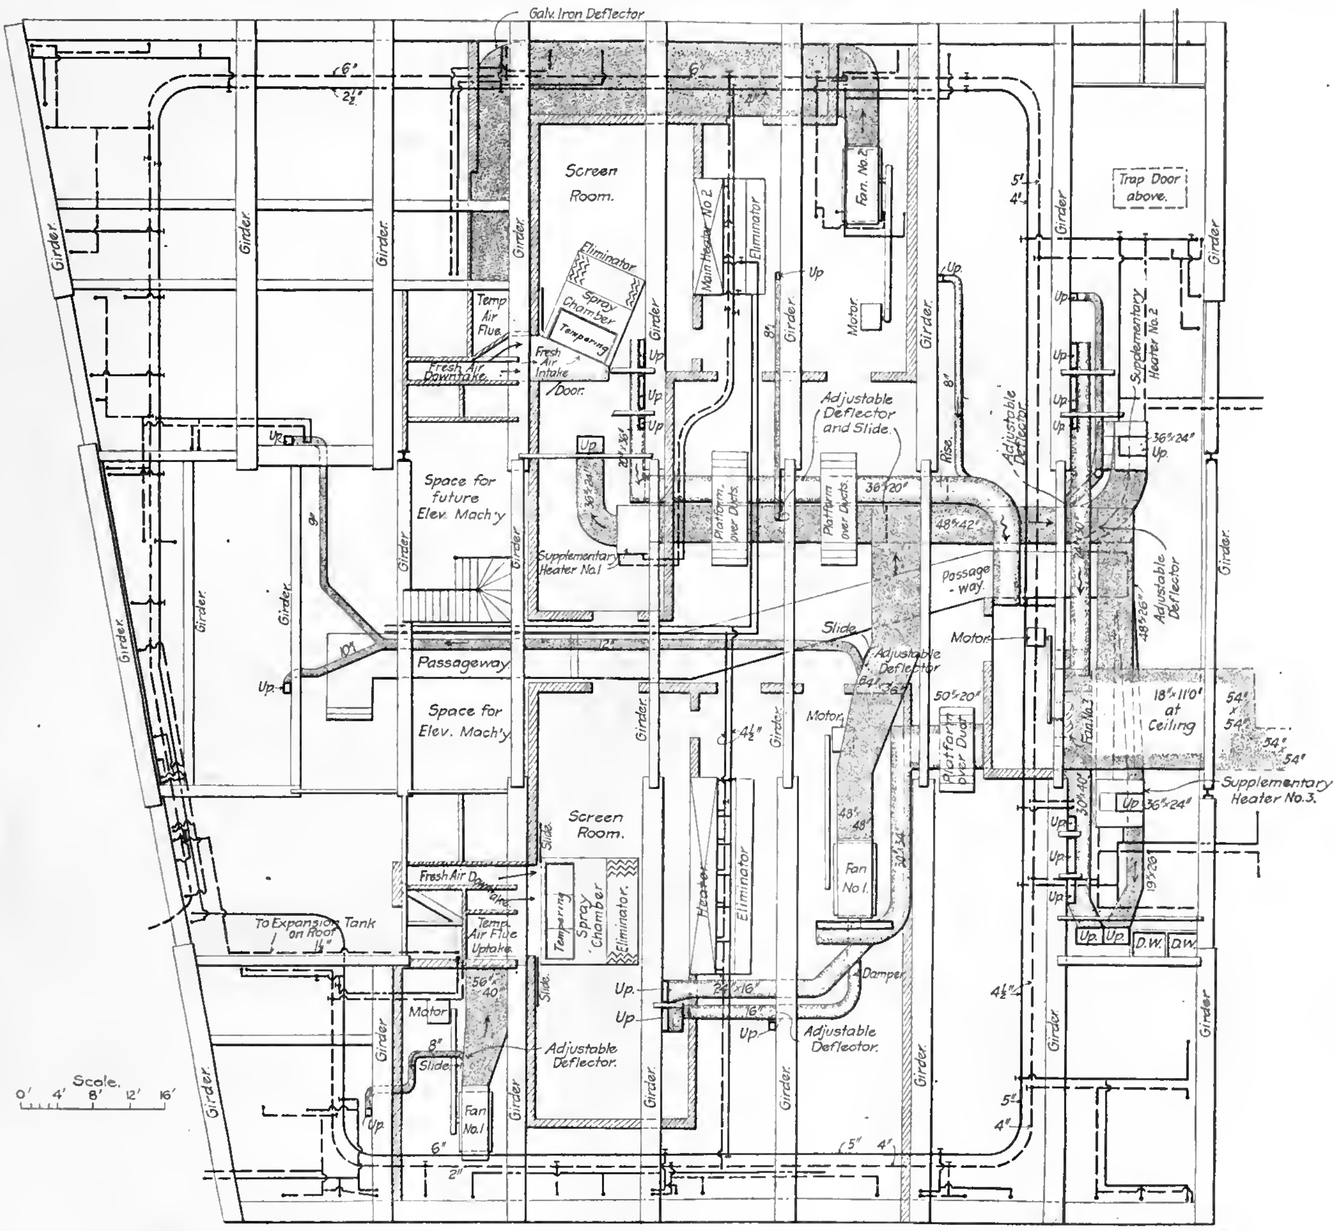
After leaving the washing apparatus the air is passed in each case through a stack of tempering radiators and then enters a fan room. The fans being located within the rooms are of the double-inlet centrifugal blower type and have a single discharge outlet connected with galvanized iron duct work for the distribution of the air. One blower is located in one room while two are in the other, one of these, No. I A, being for the waiting room system. The blowers, which are of the New York Blower Company's make, are belt driven from electric motors.

The initial tempering stacks consist of ordinary hot-water indirect radiators and are ordinarily only used when the washing apparatus might become frozen. The washing apparatus is of the R. H. Thomas patent, built by Messrs. pivots and turned by means of a connecting bar so that these baffles may be adjusted at any desired angle from 45 degrees to a line parallel with the current of air.

The main heater consists of Excelsior indirect radiators designed to warm the air to 70 degrees. Immediately beyond these, in the fan room, is a second set of eliminators, consisting of three rows of galvanized iron baffles also pivoted and connected to a controlling lever. These are intended for summer use to effect as full a separation of water from the air as possible and thus to reduce its humidity; in this connection arrangement has been made to supply the tempering coils with cold water for cooling the incoming air.

Fan No. 1 A, which supplies the waiting room, delivers chiefly to three different points between filled with granulated cork, all joints made tight by the use of elastic cement. At the ceiling of every story except that of the ground floor, the tempered air shafts connect with a duct which runs above a suspended ceiling in the corridor supplying the various offices through registers about 8 feet above the floor.

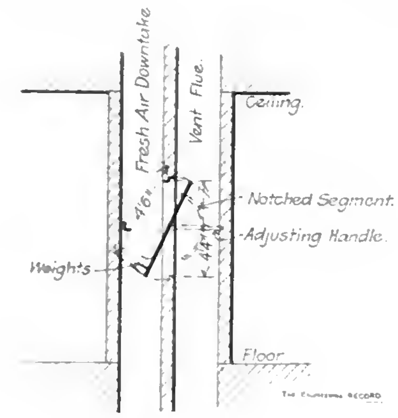
In the waiting room there are four points of egress for the air. The air is then carried along in a suspended basement ceiling duct from each point of exit and is led to an exhaust chamber of about 1,386 cubic feet capacity. In it is installed a Blackman fan belted to an electric motor. The air from this fan is delivered through a 1½x11-foot duct, which is run underneath the flooring, to a vertical flue in one corner of the trainshed, and there discharged 10 feet above the trainshed floor.



VENTILATION AND HEATING IN THE P. & L. E. R. R. STATION BUILDING, PITTSBURG.
WESTINGHOUSE, CHURCH, KERR & CO., ENGINEERS AND CONTRACTORS.

Thomas & Smith, of Chicago, and consists of a water spray chamber and an eliminator which is a collection of vertical baffles around which the air has to pass, depositing in so doing the surplus water carried in the air. The spray chamber contains four rows of spray heads forming a water curtain through which the air has to pass. The water is supplied by a direct-acting steam pump, and is caught in a steel tank on the floor of the chamber from which the water is run to waste. The sprays are enclosed in an iron casing with a thick glass window at each end. The first four rows of the eliminator are of copper tinned over, while the remainder are of galvanized iron arranged on in that room. As indicated in the basement plan, there are three supplementary heaters, each of Sterling hot-water indirect radiators, beyond which the air is lead to large registers of special design, in the waiting room, each register 16 square feet in area. The other blowers, Fans No. 1 and 2, which supply the offices throughout the building, deliver, as shown in the basement plan, to two tempered air shafts, which are carried upward through the building alongside the fresh cold-air down shafts. The proximity of these two air passages required some insulation between them. The partition consists of galvanized-iron sheets fitted on wooden frames with a 2-inch space

For the floors above the vent registers are similarly located at the floor, and the air is carried in wall flues to the suspended ceiling of the corridor. These connect with two vent flues running to the attic. There they discharge into the space over the top-story corridors and in that manner deliver the vitiated air to Fan No. 5, which is of the Blackman type. Fan No. 6 has been set above the ceiling of a kitchen in the top story on a vertical shaft, as shown in an accompanying cut, and is direct connected to a motor placed below it. A grating is provided below the latter, sufficiently strong to bear the weight of a man, and the air is admitted from below through it. The exhaust air from the adjoining dining rooms is led into the room through flaps, so as to insure an air flow in one direction only and thus to prevent the composite odors of the kitchen from diffusing through the building. In general

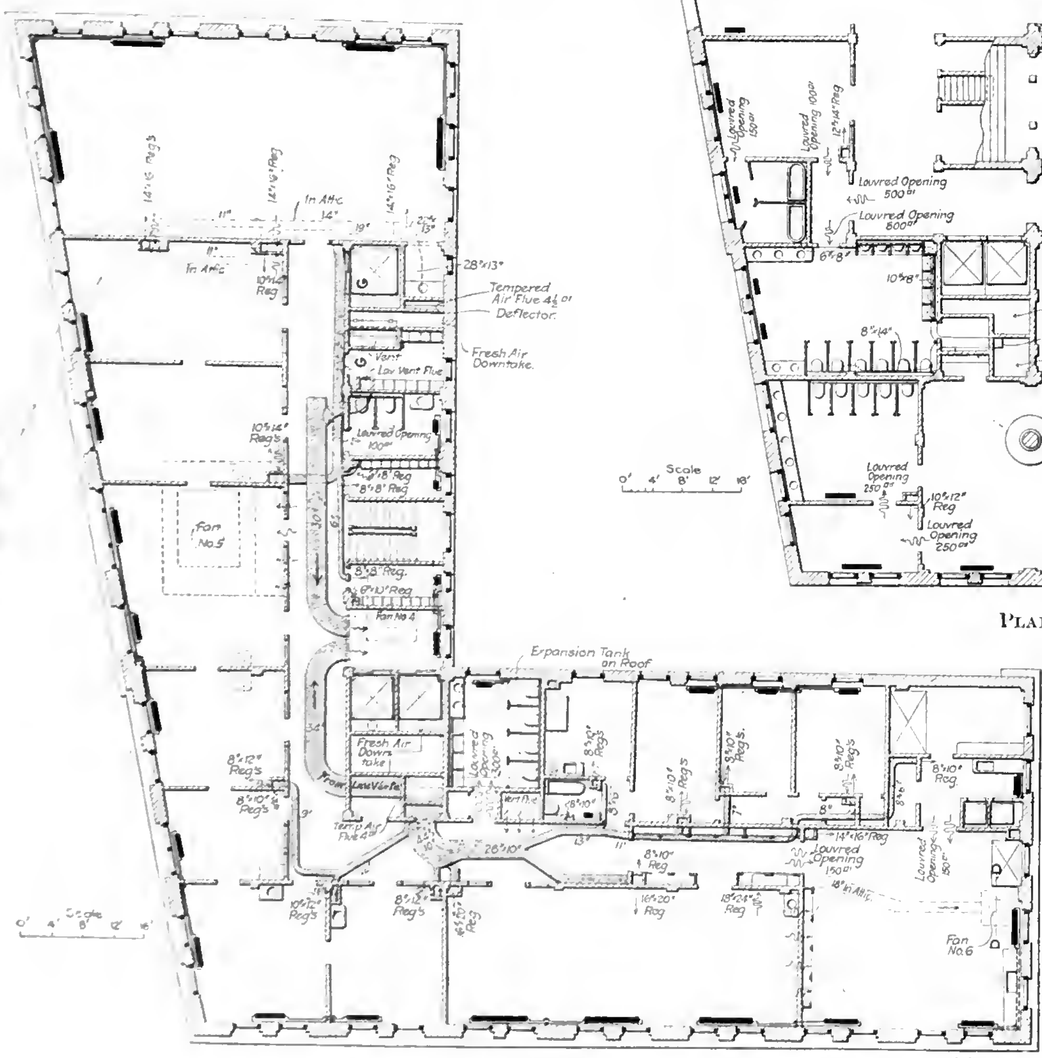


Section G-G. 6th Floor.

the air is changed once in fifteen minutes in those rooms which are continuously occupied.

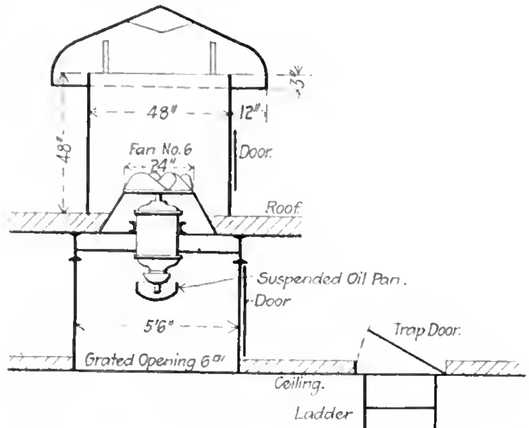
The withdrawal of air from the various toilet rooms is accomplished by a system of flues and ducts separate from the rest of the building. The air is brought to the top story in two main-vent flues, which are joined by duct work in the space over the corridor to a separate fan chamber containing Fan No. 4. This fan is also of the Blackman type. The flue connecting the fan with the outside air is of galvanized iron and is fitted with a discharge top.

The heating of the building is accomplished



PLAN OF THE TOP STORY.

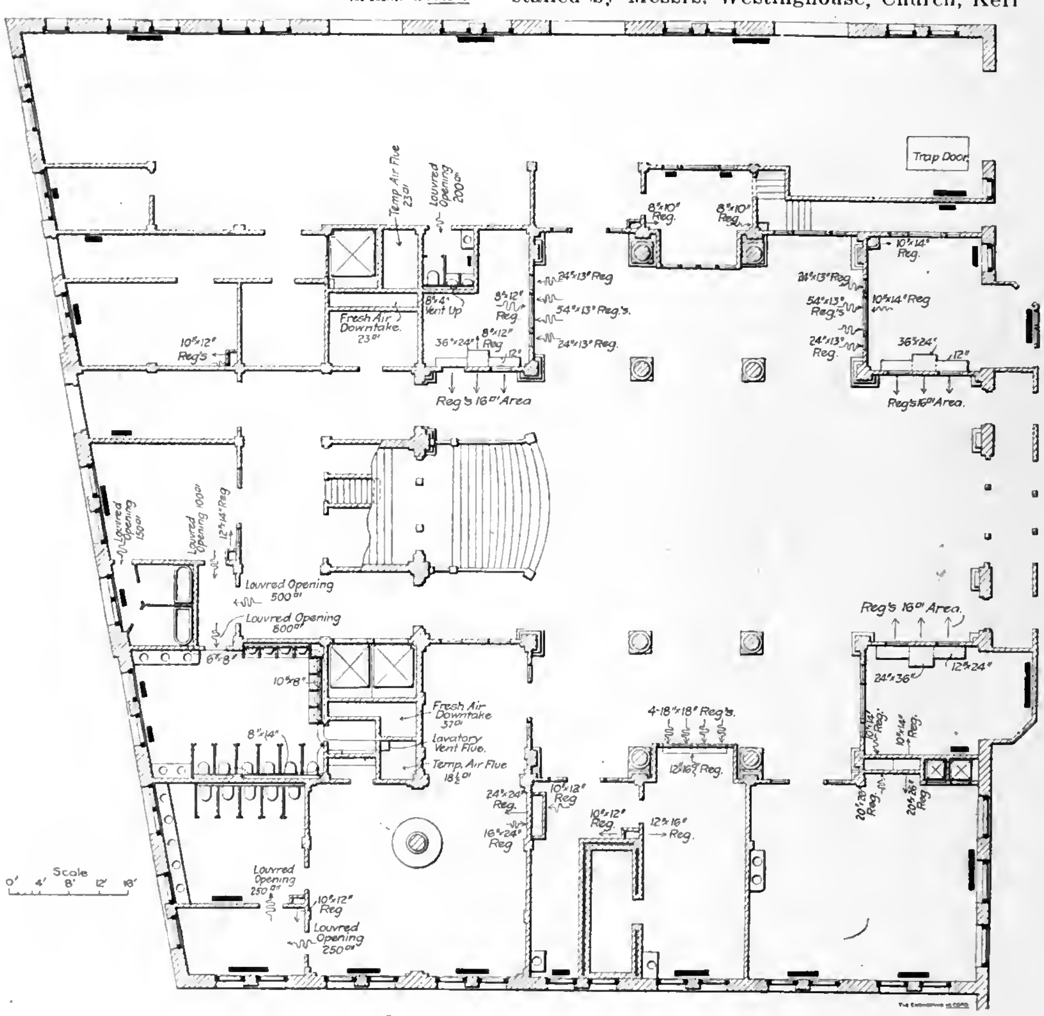
primarily, with the exception of the waiting room, which is warmed exclusively by the hot-water indirect method, through hot-water direct radiation, as already stated. Exhaust steam from engines, pumps, etc., in the powerhouse is utilized in a large heater of the closed type, also in the powerhouse, for warming the circulating water. An auxiliary heater is provided for heating the water to a higher temperature on extra cold days and when the supply of exhaust steam is insufficient. Baldwinsville centrifugal pumps, installed in duplicate



Section D-D 6th Floor Plan.

and each driven by a Westinghouse steam engine, are employed to circulate the warm water through the system. The supply and return mains at the pumps are 6 inches in diameter. The latter reach the building through a tunnel joining the power and headhouse. The supply main runs around the outside of the building wall in the basement and supplies the various riser lines for different sections of the structure as well as the tempering and heating stacks. The return main travels parallel with the flow main, the latter decreasing in size as it continues around the basement and the return main increasing in size from the first return pipe connection to its final diameter of 6 inches. The direct radiators are of the Detroit pattern and in many cases two and three radiators on each floor are connected to one pair of risers. An open expansion tank of steel is provided above the top story.

The work described was designed and installed by Messrs. Westinghouse, Church, Kerr



PLAN OF THE GROUND FLOOR.

& Company, of New York, under the supervision of Mr. J. A. Atwood, chief engineer of the Pittsburg & Lake Erie Railroad, and Mr. A. R. Raymer, assistant chief engineer.

The Admission of Trade Refuse into sewers has recently been made the subject of special regulation by the Town Council of Halifax, England, as described in "The Surveyor." The regulations provide that all liquid trade refuse from factories shall be passed through suitable settling tanks, which are to be constructed and at all times maintained by the owner. The resulting effluent is to be free from any substance which may be injurious to the sewers or the sewage, create a nuisance, or may be dangerous to health. All suds are to be treated for the removal of grease. The maximum daily quantity of effluent which may be passed from any factory into the sewer is to be agreed upon before any connection with the sewer is made.

Cellar Bracing in the New York Stock Exchange.

The New York Stock Exchange, on Broad Street near Wall Street, occupies an area approximately equal to 150 feet square and has in all fourteen floors and a roof about 140 feet in maximum height above the New Street curb. As some of the stories are merely galleries and others are below the level of the streets, the building may be considered as a ten-story structure. It is noteworthy for the spacious Board Room which occupies a large part of the whole building. The riveted steel trusses which support the upper stories have been fully described in The Engineering Record of May 17. It is also remarkable for the character and depth of its foundations and the great depth of the cellar floor below ground-water level; these foundations and the methods of constructing adopted by Mr. John F. O'Rourke, the contractor, were described in The Engineering Record of September 28, 1901. Some of the features of the special construction involved in providing suitable bracing to resist the hydraulic pressure which it was assumed might be developed against the walls below the ground-water line will be described in this article. The framework of the building is of steel and conforms to the general design indicated in the longitudinal and transverse sectional elevations published in the preceding articles, but there are so many variations and irregularities in the different stories that the design is very much complicated and cannot be advantageously farther described. Above the first floor the construction corresponds to that of ordinary steel-cage office buildings, and standard details are generally adopted for beams and columns, roof and floor design, etc. Below the basement level special bracing was introduced and interesting methods were used in the erection.

After the site was cleared it was excavated to a depth of about 20 feet below the New Street curb and a solid concrete wall 7 1/3 feet thick was carried down around these sides of the lot to the solid rock at a maximum depth of 60 feet below the New Street curb or about 48 feet below the assumed ground-water level. This wall was built in separate sections from 24 to 30 feet long and about 50 feet high, constructed in wooden pneumatic caissons, which were sunk successively in both directions from a starting point at the northwest corner. The caissons overlapped each other at the corners of the lot and the intermediate ones had closely abutting ends. The adjacent sides or ends of all the wall sections were keyed together by vertical concrete cylinders 5 feet in diameter, which united them with strong water-tight joints and practically formed a monolithic dam around three sides of the lot with its ends abutting against the adjacent side wall foundations of the Commercial Cable Building.

The caissons were carried through the hardpan, which was from 5 to 11 feet thick, and the surface of the solid rock was dressed until it was sound and satisfactory. The footings were very carefully cleaned, grouted and concreted under pneumatic pressure. A good contact and tight joint were thus obtained, and as the hardpan is very refractory and considered nearly equal to concrete the lower part of the wall was firmly secured against lateral displacement until the bracing was put in place. It may be considered as a vertical beam built in at the bottom and subjected to a horizontal distributed load due to the pressure of the ground water on the outside. When the caissons were sunk the water pressure was of course balanced on opposite sides, but when the excavation for the cellar was carried down nearly 50 feet below the water level the walls would have been subjected to a large unbalanced lateral thrust, as the water was gradually pumped down inside them.

Special observations and experiments convinced Mr. Amory Coffin, M. Am. Soc. C. E., who was in charge of the design, that no matter how slight might be the clearance between the exterior vertical surface of the wall and the earth or hardpan, the full theoretical hydrostatic pressure due to a saturated backing extending from the base to the ground-water level should be assumed as acting over the whole wetted vertical surface, and the computations were made and the structure proportioned on that basis.

As the excavation was leveled up solid with concrete to the top of the cellar floor, the part thus refilled was not considered in calculating the height and pressure of the ground water, and the wall was figured as a retaining wall 36½ feet high from cellar floor to lowest ground-water line, which varied inexplicably about 4 feet on different sides of the lot. The weight per cubic foot of the saturated backing was assumed at 120 pounds and the pressure was calculated by the empirical formula: Pressure $= \frac{1}{4} h^2 \times 120$, which gives 20 tons per lineal foot as against 20.8 tons for water pressure applied at one-third of the height from the bottom to the top, say 12 feet. The larger value was accordingly used and the resultant total pressure, applied 12 feet above the bottom, is 41,600 pounds per lineal foot. The wall has a net width, inside the caisson, of 7 1/3 feet, and assuming its weight to be 54,540 pounds per lineal foot the wall has a moment of stability of $54{,}540 \times 3\ 2/3 = 200{,}000$ foot-pounds. The moment of stability is equivalent to a moment with a horizontal force of 14,666 pounds with a lever arm of 12 feet. The center of moments was therefore taken at the inner lower corner of the wall and this horizontal force being applied at a height of 12 feet was considered as diminishing the thrust by that amount, thus leaving 24,940 pounds unbalanced thrust, equals 12.47 tons per lineal foot.

In providing resistances for this outside pressure the wall was assumed to be divided into lower, middle and upper sections by two horizontal lines 7 and 23 feet above the cellar floor. The unbalanced pressure on the upper part, about 13 feet high, averages 255 pounds per square foot and equals 1.7 tons per lineal foot, as indicated in the large diagram, and is resisted by the C tier of floorbeams. The pressure in the middle part, 16 feet high, averages 810 pounds per square foot and equals 6.48 tons, which is transmitted through horizontal distributing girders on the sides of the wall and is resisted by the beams and special struts in the A tier of floorbeams which receive equal and counterbalancing thrusts from the opposite walls and so are in equilibrium under heavy pressure. The pressure in the lower part, 7 feet high, averages 1,230 pounds per square foot and equals 4.28 tons per lineal foot, which is resisted by the shearing strength of the concrete and the efficiency of the wall in transverse flexure which transmits it to react on the bed rock. These calculations were all made on the assumption that the wall is unloaded; this was true for some time after it was built, but before the excavation was completed and the maximum hydrostatic pressure was developed, the superstructure was commenced, and this added materially to the weight and stability.

The interior columns of the building are arranged in six north and south rows and four east and west rows, and all of them have concrete footings carried down to solid rock at about the same depth as the outer dam, in wooden pneumatic caissons, surmounted by removable wooden cofferdams, most of which were cylinders from 6 to 8½ feet in diameter and nearly 40 feet high above the top of the concrete pier at the bottom. After the interior piers were built up to the proper level they were capped by I-beam grillages and the steel columns were erected on these inside the protecting cofferdams, the column bases being about 38 feet below the level of the ground water. The D tier of beams, about 42 feet above the cellar floor and 5 feet above the ground-water line, was first erected and forms the basement floor; afterwards the beams, girders and struts at the C B and A levels were erected by special methods as the excavation advanced.

Sumps were dug and several steam pumps installed which gradually removed the water from within the outer walls or dams, and as these were efficient in excluding the outside water the ground-water level was gradually lowered and the excavation carried down to the hardpan through soft wet mud.

At about the level of the C tier there was an old safe-deposit vault about 110 feet long from east to west, 23½ feet wide and 9 feet high. It was built of granite and wrought iron, had an estimated weight of 1,200 tons and rested directly on the earth and sand just above the water level. The lower rows of columns were arranged to clear this structure, and when they had been erected a continuous line of box girders was set on the caps of the row on the south side. A similar line of girders was set on top of the next row of columns to the south, both lines of girders not being parallel but reaching nearly across the lot from west to east. The girders support 18-inch transverse I-beams which rest across their top flanges and carry longitudinal I-beams for the floor of a new steel vault, which was built to replace the old one and receive its contents before the latter was removed.

The water was pumped down as far as possible in the excavation and narrow transverse drifts were made in a north and south direction below the original water line in the soft mud under the old vault. Temporary 24-inch I-beams about 7 feet apart were worked into the drift and wedges driven above them to support the vault. Their south ends were seated on the north line of box girders between the 18-inch permanent I-beams, and their north ends were supported on vertical wooden shores and blocking. The excavation was then continued under the old vault and all the earth removed for several feet below it, so that space was afforded to set the permanent beams and girders of the C tier. These were supported on the tops of the lower sections of two north and south rows of columns parallel to and just beyond the walls of the old vault. The vault walls were not parallel to the rows of columns in the upper tiers of the new building so that it was necessary to offset the upper sections of these columns from the lower sections and the latter were capped with beam box-girders, on the upper flanges of which were seated the upper sections of the columns from 1 to 5 feet eccentric with their corresponding lower sections. Some of these columns interfered with the old walls and slots had to be cut in the masonry to receive and permit the erection of the superstructure before the old vault was vacated.

After the completion of the C tier of beams and girders the excavation was continued about 15 feet deeper to the bottom of the A tier, the outer concrete walls being unsupported and subjected to an unbalanced outside pressure which was resisted by the transverse strength of the concrete. The wooden lagging of the inner sides of the cofferdams was removed, exposing the concrete surface, and double-web horizontal distributing girders were set parallel to the wall and about 3 inches clear of it. They were suspended from the C tier by pairs of ¾-inch vertical screw-rods engaging 4x3-inch oak cross pieces or saddles under the girders. Lines of horizontal struts in the planes of both rows of columns were then set across the lot at the level of the distribution girders and were field-riveted to the columns at their intersections and took bearing on the girders. After the bracing system was complete horizontal boards were fitted between the lower edges of the girders and the face of the wall and concrete was rammed in solidly between the girder and the wall to make a continuous bearing. Open holes about two inches by four placed eight feet apart were made in the concrete and asphalted to serve as weep holes to drain any water that might collect on the face of the wall through the lower story.

The columns were set so accurately and were so correctly made at the shops that no reaming in the field was necessary to fit the rivet holes in the connecting struts. As the columns were set a long time in advance at the bottom of deep wells, and were rigidly connected by the upper tiers of beams before these struts

CELLAR BRACING IN THE NEW YORK STOCK EXCHANGE.

MR. GEORGE B. POST, ARCHITECT; MR. AMORY COFFIN, ENGINEER.

were assembled to them, this fact reflects great credit on the excellence of the leveling and alignment by the contractor's engineer, Mr. John C. McCord, and his foreman, Mr. Frank Harbison.

The B tier was erected simultaneously with the A tier but was not a full tier and was not calculated to receive any thrust from the walls. It was not continuous across the building but extended only over the boiler room and could not therefore transmit the thrust to an equal reaction. After the A tier was finished, the excavation was completed to hardpan and was leveled up with broken stone from 2 to 5 feet thick, in which were laid 2-inch tile drain pipes with open joints all pitching to a collecting basin in the center of the lot. This basin is a bell-shaped casting 3½ feet in diameter at the bottom and 3½ feet high. The bottom is open with an outside horizontal flange seated on the rock, and the top has a manhole and cover 16 inches in diameter at the level of the cellar floor in which it is set. The sides are perforated with 180 staggered 1-inch holes in nine horizontal rows, through which the water collected by the drain pipes enters and is pumped out when necessary. The excavation has been completed for several months and very little pumping has been required. On top of the stone filling there is 6 inches of concrete, then a water-proofing layer of five-ply felt laid in hot tar and flashed up to the water level on the facing of the outside walls. The facing is of common red bricks, and is really a separate wall 8 inches thick and 4 inches clear of the concrete dam-wall, leaving an air space between them in which any seepage or leakage water can collect and drain off to the sump through the open tile pipes.

On the south side of the lot the excavation was bounded by the caissons of the Commercial Cable Building, but the old wall adjacent to that had been underpinned by cylinder piers sunk by the Breuchaud process to bed rock when the Commercial Cable Building was built. These piers were allowed to remain under the new wall and lintels were put across them to carry the masonry above their tops. The new wall is about 3 feet thick at the base, completely enclosing the cylinders, and the horizontal distributing girders on its face receive the thrust from the caissons of the Commercial Cable Building, which counterbalances the pressure from the opposite side.

The general dimensions and arrangement of the distributing girders and reaction struts in tier C are shown by the diagram on tier A, which is typical of the whole tier. On the north side of the building tier C supports the sub-basement floor and its girders and beams act as struts. One panel of the A tier is X-braced with 1½-inch square rods with clevis ends pin-connected to horizontal plates which are riveted in the angles between transverse and longitudinal struts and serve as knee-braces to stiffen them laterally. Where the rods intersect they have pin connections to the ends of 7x1-inch flat bars which allow them to cross without too much eccentricity. The other panels of this tier are unbraced except by the floorbeams and hollow tile and concrete floor construction.

The detail given of column 22 and its connections is typical of the general features of the columns and struts at the A tier. All the struts are made of pairs of channels with top and bottom cover plates and closed rectangular cross-sections. The east and west girders B B have jaws which are field-riveted to the vertical plates on the faces of the columns, and, as the channels are not wide enough to receive a sufficient number of rivets, they are extended and at the same time their flanges are directly connected by side angles riveted on the tops and bottoms and serving to extend the cover plates. The north and south struts A A have drop ends which serve as knee-braces to resist sway strains, and have vertical flange angles field-riveted to the faces of the columns.

The outer ends of the struts take bearing against the cover plates of the distributing girders with flat base plates bolted to them as indicated in the detail of the strut marked D in the general plan. Where the struts abut on the ends of two girders of unequal depth, as at D, the shallow girder is filled out with a webbed casting.

The lighter distributing girders are made with a pair of I-beams and two cover plates, as shown in the detail of girder E. At the ends where the struts take bearing they are reinforced by web-stiffener angles riveted across the I-beams and having their ends milled to bear on the flanges. All the distributing girders are supported on brick piers built up from the cellar floor like buttresses on the face of the inner wall and terminating at the under sides of the girder. At the corners of the cellar, the east and west girders are connected to the north and south girders with notched joints, as shown in the detail of girder H, which is similar to girder F, shown on the general plan, but is on the opposite side of the building.

A very interesting feature of this building is the well in which the plunger for the direct-acting ram of the sidewalk ash-elevator is operated. This required to be sunk to a long distance below the cellar floor and a hole 14 inches in diameter and 36 feet deep was drilled through the solid rock by a Calyx drill. The core was broken out and removed by the drill bit and the hole has smooth true walls and is used without lining. A similar well 14 inches in diameter and 7½ feet deep was drilled in another part of the cellar by the same machine to receive the plunger of the coin-lift. The drilling was done by the Otis Elevator Company.

For the information given in this article The Engineering Record is indebted to Mr. George B. Post, architect, and to Mr. Amory Coffin, engineer for the structural masonry and steel work of this building.

A List of Bids Received by the Corps of Engineers, U. S. A., during the fiscal year ending June 30, 1901, has been published as House Document 161 of the first session of the 57th Congress. It gives the full tenders for works, material and labor received during the year.

Condensing Water Pumps of an unusual type, employed in the power station of the Newcastle, England, street railway, were described by Mr. Charles Hopkinson in a paper before the Institution of Civil Engineers. Cooling towers could not be used for legal reasons, and satisfactory tenders for a plant with reciprocating pumps were not received, so a unit was adopted consisting of a centrifugal pump, electric motor and turbine, mounted on a single shaft with the motor in the middle. The pump runner is 23⅝ inches in diameter and receives its supply from a suction pipe on each side, so as to avoid any axial thrust in the shaft; while the turbine has a 13½-inch runner and discharges through two draft tubes, arranged one on each side for the same purpose. The axis of the pump shaft is 8¼ feet above the mean water level of the river from which the water is drawn, and 78¾ and 90¾ feet below the condensers. The return water from the condensers passes through the turbine and saves about 42½ per cent. of the power needed to circulate the water were it not employed.

An Important Decision Concerning River Pollution by Sewage.

Condensed from decision of Ohio Supreme Court, in Balliett vs. City of Mansfield, 63 N. E. Rep. 86.

The plaintiff sued for alleged violations, by the defendant, of his rights as a riparian proprietor. He is owner of two valuable farms, by or through which runs a small natural water course, known as the Rocky Fork of the Mohican River. Both of the farms are naturally adapted to, and have been used for, agricultural and grazing purposes. Each farm is improved, and each has on it a dwelling house, barn, and other suitable buildings. One of them, known in the case as the "home" farm, is occupied by the plaintiff as his family residence, and had been for many years before the alleged encroachments on his rights by the defendant. The other he rents to tenants, who occupy and cultivate it. The waters of this natural stream were accustomed to flow by and through these farms, supplying them and their occupants with pure and wholesome water in sufficient quantities for all domestic, agricultural, and other suitable purposes for which pure and wholesome water is generally used and needed upon a farm, until they were polluted and corrupted by the alleged acts of the defendant.

The wrong complained of is, that the defendant, a city of something over 18,000 inhabitants, and situated on or near the water course above the plaintiff's farms, by a system of sewerage emptying into the stream, caused to be collected and discharged into the stream the sewage of the city, or a large part of it, which was carried down the stream to the plaintiff's farms, where it accumulated and remained in large quantities. As a result of this alleged wrong of the defendant, the water was polluted, and rendered unfit for domestic and other ordinary uses; and, in time of freshets, the filth was washed out by the force of the stream and deposited on the plaintiff's lands, destroying the grass and herbage, and causing offensive and unwholesome smells, which materially interfered with the comfortable and proper enjoyment of the premises by the plaintiff and his family.

The suit was defended chiefly on the ground that the stream was corrupted, in part at least, by other independent sources, over which the defendant had no control; though the contention apparently most relied on in argument here is that the city cannot be held liable for the acts complained of, in any event. In the court's instructions to the jury the defendant's liability was confined to such substantial injury as the plaintiff actually sustained in consequence of the alleged misconduct of the defendant, and his measure of recovery, if the issues were found in his favor, was limited to such an amount as would reasonably compensate him for the material interference with the comfortable enjoyment of his home farm, the proper and necessary use of the water to which he had hitherto been accustomed, including any additional expense rendered necessary in watering his stock, and the loss of his grass and herbage. His damages to the rented farm, the jury were instructed, could not exceed the actual loss resulting from a diminution in the rents. The charge given covered, substantially, all of the instructions requested by the defendant, except, probably, the second one, which reads as follows: "The right of plaintiff to have the water descend on him in its pristine clearness must yield to the demands of a denser population and the march of civilization."

So that it must be accepted as established by the verdict and judgments below that the injury of which the plaintiff complains was caused by the defendant, as claimed, and that, in consequence thereof, he sustained substantial damage of that special nature and degree which would enable him to maintain action therefor if inflicted by an individual or private corporation. And he is not without like remedy against the defendant, unless, as claimed by its counsel, it has a paramount right, either by legislative grant, or from necessity for the preservation of the public health, safety and welfare, to subject the water course to the uses it has made of it, without accountability for the destruction or material impairment of the property rights of lower riparian owners.

The statutory authority for this immunity, it is contended by counsel, is found in sections 2232 and 2370, of the Revised Statutes. The former section provides that a city may enter upon and hold real estate without its corporate limits, among other enumerated purposes, "for sewers, drains and ditches, and for this purpose the corporation shall have power to appropriate, enter upon and take private property, lying outside of the corporate limits." The latter section authorizes municipal corporations to adopt a system of sewerage, "the main or principal sewers having their outlet in a river or other proper place."

The lawful exercise of the power conferred on municipal corporations to enter upon and take private property for any of the purposes enumerated by the former section requires a legal appropriation, as that section indicates, involving the assessment of compensation for the property when taken without the owner's consent. The stream in question in this case is not a river, a term that may import a stream of sufficient volume and flow to carry off sewage emptied into it, and thus preserve the purity of its water; nor, as will be hereafter noticed, can that be a suitable place for the deposit of sewage, within the contemplation of the law, where that will result in the creation of a public or private nuisance. But the right of the plaintiff to redress for the injury done him lies back of any mere authorization by the statute of the defendant's acts which inflicted the injury, and rests upon the constitutional guaranty which secures the inviolability of private property, and the right of the owner to compensation when taken for any public use. Indeed it appears to be a settled principle of universal law, independent of constitutional provision, that the right to compensation for private property when taken for a public use is an inseparable incident of the ownership of property.

It is declared in Pumpelly v. Canal Co., 80 U. S. 166, that: "By the general law of European nations and the common law of England it was a qualification of the right of eminent domain that compensation should be made for private property taken or sacrificed for public use. And the constitutional provisions of the United States, and of the several States, which declare that private property shall not be taken for public use without just compensation, were intended to establish this principle beyond legislative control." And it was there held that: "It is not necessary that property should be absolutely taken, in the narrowest sense of that word, to bring the case within the protection of this constitutional provision. There may be such serious interruption to the common and necessary use of property as will be equivalent to a taking, within the meaning of the constitution. The backing of water so as to overflow the lands of an individual, or any other superinduced addition of water, earth, sand, or other material or artificial structure placed on land, if done under statutes authorizing it for the public benefit, is such a taking as by the constitutional provision demands compensation."

In that case, a statute of Wisconsin authorized the construction of a dam across Fox River, in order to improve its navigation. The dam, which was constructed in accordance with the provisions of the statute, caused the water to overflow the plaintiff's lands, on account of which he suffered substantial injury, for which he brought suit. It was claimed by the defendant that the damages sustained by the plaintiff were "such as the State had a right to inflict in improving the navigation of Fox River, without making any compensation for them." Mr. Justice Miller, in resolving this contention against the defendant, said: "The argument of the defendant is that there is no taking of the land within the meaning of the constitutional provision, and that the damage is a consequential result of such use of a navigable stream as the government had a right to for the improvement of its navigation. It would be a very curious and unsatisfactory result if, in construing a provision of constitutional law always understood to have been adopted for protection and security to the rights of the individual as against the government, and which has received the commendation of jurists, statesmen and commentators, as placing the just principles of the common law on that subject beyond the power of ordinary legislation to change or control them, it shall be held that if the government refrains from the absolute conversion of real property to the uses of the public it can destroy its value entirely, can inflict irreparable and permanent injury to any extent, can, in effect, subject it to total destruction, without making any compensation because, in the narrowest sense of that word, it is not taken for the public use. Such a construction would pervert the constitutional provision into a restriction upon the rights of the citizen, as those rights stood at the common law, instead of the government, and make it an authority for invasion of private right under the pretext of public good, which had no warrant in the laws or practices of our ancestors." And the learned justice, referring to the case of Gardner v. Newburgh, 2 Johns. Ch. 162, observed that: "In the case of Gardner v. Newburgh, Chancellor Kent granted an injunction to prevent the trustees of Newburgh from diverting the water of a certain stream flowing over plaintiff's land from its usual course, because the act of the legislature which authorized it had made no provision for compensating the plaintiff for the injury thus done to his land. And he did this though there was no provision in the constitution of New York such as we have mentioned, and though he recognized that the water was taken for a public use. After citing several continental jurists on this right of eminent domain, he says that while they admit that private property may be taken for public uses when public necessity or utility requires, they all lay it down as a clear principle of natural equity that the individual whose property is thus sacrificed must be indemnified. And he adds that the principles and practice of the English government are aqually explicit on this point. It will be seen in this case that it was the diversion of the water from the plaintiff's land which was considered as taking private property for public use, but which, under the argument of the defendant's counsel, would, like overflowing the land, be called only a consequential injury." And Mr. Justice Miller concludes that: "If these be correct statements of the limitations upon the exercise of the right of eminent domain, as the doctrine was understood before it had the benefit of constitutional sanction, by the construction now sought to be placed upon the constitition it would become an instrument of oppression rather than protection to individual rights. But there are numerous authorities to sustain the doctrine that a serious interruption to the common and necessary use of property may be, in the language of Mr. Angell in his work on water courses, equivalent to the taking of it, and that under the constitutional provisions it is not necessary that the land should be absolutely taken."

Authors who have fully investigated the subject are quite agreed in their conclusions that riparian rights are property rights, and therefore property, in the legal signification of the term, and within the meaning of the constitution.

In 1 Lewis, Em. Dom. Sec. 60, that author says that, "All the authorities agree" that small streams incapable of navigation "are wholly private property, and that the title of the riparian owner extends to the middle of the stream." And in section 61 it is said that, "It may be laid down as a well-settled principle that every proprietor over or past whose land a stream of water flows has a right that it shall continue to flow to and from his premises in the quantity, quality and manner in which it is accustomed to flow by nature, subject to the right of the upper proprietors to make a reasonable use of the stream as it flows past their land. This right is a part of his property in the land, and in many cases constitutes its most valuable element. It necessarily follows, therefore, that any violation of this right in the exercise of the power of eminent domain is a taking of private property for which compensation must be made." In section 62, the rule is stated as follows: "Where the waters of a stream, or any part thereof, are taken or diverted to supply a city or village with water, or for the use of a canal or railroad company, or to improve a highway by land, or to make a new channel, either for the improvement of navigation or for the protection of a public road, or for any other public use, compensation must be made to the inferior proprietors on the banks of the stream who are injured thereby. The only dissenting case which has come to our notice is that of Commissioners v. Withers, 29 Miss. 21, 64 Am. Dec. 126, in which the supreme court of Mississippi held that it was not a taking to divert a stream of water from the plaintiff's property into a new channel for the purpose of improving navigation. This decision is so palpably wrong that we do not think it requires discussion." "According to principles heretofore laid down," says the same author, in section 84, "it follows that an injury to riparian rights for public use is a taking for which compensation must be made. 'These riparian rights founded on the common law are property, and are valuable, and, while they must be enjoyed in due subjection to the rights of the public, they cannot be abridged or capriciously destroyed or impaired. They are rights of which, when once vested, the owner can only be deprived in accordance with the law of the land, and, if necessary that they be taken for public use, upon due compensation.' "

In Mills, Em. Dom., where the same doctrine is maintained, it is said, section 79, that: "Riparian rights are property. Of this property the owner cannot be deprived without just compensation, nor can the State itself exercise such a power of deprivation, or confer it upon some subordinate municipality, without making compensation for the property taken." And in section 182 of the same work it is laid down as settled law that: "The legislative authority to do an act resulting in damages to the property of an individual cannot be sustained, without the payment of damages, on the simple claim that the legislature cannot authorize that which is improper. It is beyond the power of the legislature to authorize the infliction of an injury without compensation. Charters should not be construed as evincing any legislative intention to authorize an injury, or to shield the corporation from a common law action, in case compensation is not provided. The fact that compensation is not provided should not lead the court to suppose that all injuries not provided for were declared by the legislature to be consequential, and therefore not subject to compensation."

In Gould, Waters, Sec. 204, after declaring the right of riparian proprietors to have the stream "flow as it is wont by nature, without material diminution or alteration," it is maintained that: "They may insist that their rights to thus use the water shall be regarded and protected as property. The right to use the water in its natural flow is not a mere easement or appurtenance, but is inseparably annexed to the soil itself. It does not depend upon appropriation or presumed grant from long acquiescence on the part of other riparian proprietors above and below, but exists jure naturæ as parcel of the land."

Wood, Nuis. Sec. 332, speaking of the property rights of riparian owners, says they are rights "in the owner of the soil which cannot be violated with impunity; rights which are distinct from those enjoyed by the public generally, and which exist, not because of any special property in the water, but because of the ownership of the land over or through which it flows, and the rights that are necessarily created thereby." These property rights, it is said in the next section, "may be the subject of sale or lease like the land itself." And in section 427, speaking more directly to the question involved in this case, the author says: "The pollution of water by artificial drainage which causes sewerage to flow into a stream, spring or well, whether done by a municipal corporation or an individual, constitutes a nuisance which entitles the owner to damages therefor, the rule being that a municipal corporation has no more right to injure the waters of a stream or the premises of an individual than a natural person."

This subject is discussed in Ang. Water Courses, where the doctrine announced in the quotations already made from other standard authors is fully upheld. In sections 457, 458, that author says: "Among the variety of legal titles which, in this country, have often been involved in controversies respecting the rights of riparian proprietors on inland streams and rivers, is the important one entitled 'eminent domain,' or the right which the government retains over the estates of individuals to appropriate them to public use. It is obvious that the government of no state can administer its public affairs in the most beneficial manner to the community at large if it cannot, on particular emergencies and for public utility, exercise at least a qualified power of disposing of, or of impairing in value, the property of an individual citizen. To this power, according to Vattel, 'men have impliedly yielded, though it has not been expressly reserved.' But it is a rule founded in equity, and is laid down by jurists as an acknowledged principle of universal law, that a provision for compensation is a necessary attendant on the due exercise of the power of the lawgiver to deprive an individual of his property without his consent." Section 458: "In England, notwithstanding the transcendent power of its parliament, the law on this subject has been administered on the above just and equitable principles. In the familiar instance of an act of parliament for promoting some specific object or undertaking of a public nature, as a turnpike, navigation, canal, or railway, the legislature scruple to interfere with private property and compel the owner of the land to alienate it, without providing a reasonable price and compensation for so doing. 'If a new road,' says Blackstone, 'were to be made through the grounds of a private person, it might perhaps be extensively beneficial to the public; but the law permits no man, or set of men, to do this without consent of the owner of the land.' In vain may it be urged that the good of the individual ought to yield to that of the community, for it would be dangerous to allow any private man, or even public tribunal, to be the judge of this common good, and to decide whether it be expedient or no. Besides, the public good is in nothing more essentially interested than in the protection of every individual's private rights, as modeled by the municipal law. In this and in similar cases the legislature alone can, and, indeed, frequently does, interpose, and compel the individual to acquiesce. But how does it interpose and compel? Not by absolutely stripping the subject of his property in an arbitrary manner, but by giving him a full indemnification and equivalent for the injury thereby sustained. The public is considered as an individual, treating with an individual for exchange. All that the legislature does is to oblige the owner to alienate his possessions for a reasonable price, and even this is an extension of power which the legislature indulges with caution."

It would not be a profitable extension of this opinion to quote from the numerous cases cited in the text-books already extensively quoted to sustain the text. The substance of the many learned opinions of able courts is given in the quotations already made. We will add to them only a brief extract from the able opinion of Ruger, C. J., in Seifert v. City of Brooklyn, 4 N. E. 321, 324, "It is a principle of the fundamental law of the State," says that learned judge, "that the property of individuals cannot be taken for public use except upon the condition that just compensation be made therefor, and any statute conferring power upon a municipal body, the exercise of which results in the appropriation, destruction or physical injury of private property by such body, is inoperative and ineffectual to protect it from liability for the resultant damages, unless some adequate provision is contained in the statute for making such compensation. The immunity which extends to the consequences, following the exercise of judicial or discretionary power, by a municipal body or other functionary, presupposes that such consequences are lawful in their character, and that the act performed might in some manner be lawfully authorized. When such power can be exercised so as not to create a nuisance, and does not require the appropriation of private property to effectuate it, the power to make such an appropriation or create such nuisance will not be inferred from the grant. Where, however, the acts done are of such a nature as to constitute a positive invasion of the individual rights guaranteed by the constitution, legislative sanction is ineffectual as a protection to the persons or corporation performing such acts from responsibility for their consequences. It has been sometimes suggested that the principle illustrated in the maxim, 'Salus populi est suprema lex,' may be applied to and will shield the perpetrators from liability for damages arising through the exercise of such power, by a municipal corporation; but we apprehend that this maxim cannot be thus invoked. The cases where such a doctrine can be properly applied must, from the very nature of the principle, be confined to circumstances of sudden emergency, threatening disaster, public calamity, and precluding a resort to remedies requiring time and deliberation. Whart. Leg. Max. 89; Mayor, etc., v. Lord, 17 Wend. 285. It is suggested in the latter case that even in such an event, under the principles of the constitution, the public would be liable for the damages inflicted. However this may be, we are quite clear that the theory that a municipal corporation has the right, in prosecuting a scheme of improvements, to appropriate without compensation, either designedly or inadvertently, the permanent or occasional occupation of a citizen's property, even though for the public benefit, cannot be supported upon the principle referred to. If the use of such property is required for public purposes, the constitution points out the way in which it may be acquired, when there is no such imminence in the danger apprehended as precludes a resort to the remedy provided, and the only mode by which it can be lawfully taken in such cases is that afforded by the excuse of the right of eminent domain."

There appears to be no diversity of opinion upon the proposition that riparian rights are property that may be the subject of bargain and sale, either with or separate from the land; that these rights constitute a part of the owner's estate in the land, and materially enter into the actual value; and that any injurious invasion or impairment of those rights amounts to a taking of the owner's property. It follows that no legislative sanction can justify the taking of such property, either directly or indirectly, though it be required for a public use, without adequate provision for a just indemnity to the owner. To entitle the owner to such indemnity, it is not necessary that his entire interest in the particular property be taken. The value of property consists in the owner's absolute right of dominion, use, and disposition for every lawful purpose. This necessarily excludes the power of others from exercising any dominion, use, or disposition over it. Hence, any physical interference by another with the owner's use and enjoyment of his property is a taking, to that extent. To deprive him of any valuable use of his land is to deprive him of his land, pro tanto. So that the principle of the constitution is as applicable where the owner is partially deprived of the uses of his land as where he is wholly deprived of it. Taking a part is as much forbidden by the constitution as taking the whole.

There is a line of authorities which sustains the right of action in cases like the one before us, and places it upon the ground that such acts as those complained of here constitute a nuisance, which municipal corporations cannot, any more than individuals, be allowed to create or maintain. To this proposition, Judge Dillon, in his work on Municipal Corporations, section 1047, adds the weight of his great authority: "It is, perhaps, impossible to reconcile all of the cases on this subject, and courts of the highest respectability have held that if the sewer, whatever its plan, is so constructed by the municipal authorities as to cause a positive and direct invasion of the plaintiff's private property, as by collecting and throwing upon it, to his damage, water or sewage which would not otherwise have flowed or found its way there, the corporation is liable. This exception to the general doctrine, when properly limited and applied, seems to be founded on sound principles, and will have a salutary effect in inducing care on the part of the municipality to prevent such injuries to private property, and will operate justly in giving redress to the sufferer if such injuries are inflicted. Accordingly, though a municipality having the power to construct drains and sewers may lawfully cause them to be built so as to discharge their refuse matter into the sea, or natural stream of water, yet this right must be so exercised as not to create a nuisance, public or private. If a public nuisance is created, the public has a remedy by a public prosecution; and any individual who suffers special injury therefrom may recover therefor in a civil action. If, therefore, deposits from sewers constructed by a city cause a peculiar injury to the owner of a wharf or dock, by preventing or materially interfering with the approach of vessels and the accustomed and lawful use of the wharf or dock, the city is liable to the latter in damages."

In Wood, Nuis. Sec. 427, the rule is stated as follows: "The pollution of water by artificial drainage which causes sewage to flow into a stream, spring, or well, whether done by a municipal corporation or an individual, constitutes a nuisance which entitles the owner to damages therefor, the rule being that a municipal corporation has no more right to injure the waters of a stream or the premises of an individual than a natural person. . . . The pollution of water by discharging waste from mills and manufactories, or, indeed, in any way, creates an actionable nuisance, and the legislature has no power to authorize the pollution of the water of a stream without compensation to the owners of the land through which such stream flows, as such use is a taking of property, within the meaning of the constitution. It has been held in numerous cases that a municipal corporation is liable for the wrongful diversion of surface water from its natural channel to the premises of another, as well as for discharging its drainage or sewage upon private property."

Other commentators of acknowledged authority maintain the same rule. A few only, of the many reported cases which sustain this doctrine, will be noticed.

The case of Chapman v. City of Rochester, 18 N. E. 88, is not substantially different from the one before us. There "plaintiff owned and occupied certain premises, across which ran a stream fed by springs of pure water. He collected the water of said stream into an artificial basin, and used it for domestic purposes and the propagation of fish, and in winter procured from it a supply of ice. Defendant thereafter constructed sewers, through which not only surface water, but the sewage from houses and water closets, was discharged into said stream above plaintiff's land, rendering its water unfit for use, and covering its banks with filthy and unwholesome sediment. Held that these acts constituted a nuisance to restrain which, as well as to recover his personal damages, plaintiff could maintain an action."

Morgan v. City of Danbury, 35 Atl. 499, is much like the preceding case. There "the plaintiff, a riparian mill proprietor, alleged that the defendant, without making him any compensation or attempting to acquire any of his rights, was discharging and threatened to continue to discharge in still greater quantity, waste matter, sewage, and other noxious, corrupt, and impure substances from its sewers into the stream, so as to pollute it and seriously damage his land and mill privilege; that such discharge poisoned and corrupted the air of the neighborhood and endangered the health of the plaintiff, his workmen, and others, and had already partly filled his dam with filth and prevented him from disposing of his land for building purposes; and prayed for an injunction against the continuance of the nuisance, and to restrain the pollution of the waters of the stream. The trial court found these allegations to be true, that the plaintiff's injuries could not be adequately compensated in damages, and that the acts complained of constituted a public nuisance, and granted an injunction restraining the defendant, after 20 months from the date of the decree, from discharging any sewage into the stream above the plaintiff's premises, and from polluting the waters by any such discharge." And it was there held "that the right to deposit a thing in any place must always be dependent, not only on the nature of the thing deposited, but on the nature of the place in question and the uses to which that has already been put; and that if the stream was, from whatever cause, in such a condition that the defendant's discharge of sewage there worked a nuisance, it had no right to use the stream for such purpose."

And see Seifert v. City of Brooklyn, supra; City of Jacksonville v. Doan, 33 N. E. 878; Inman v. Tripp, 11 R. I. 520; Good v. Altoona City, 29 Atl. 741; Owens v. City of Lancaster, 37 Atl. 858; Mason v. City of Mattoon, 95 Ill. App. 525.

The right of the plaintiff to the relief awarded him by the judgments of the lower courts is sustained by the case of Rhodes v. City of Cleveland, 10 Ohio, 160. That suit was brought against the city to recover damages for so cutting its drains as to cause the water to overflow and wash away the plaintiff's lands. The trial court charged the jury that the plaintiff could not recover, "unless he showed, either that the city acted illegally, or, if within the scope of authority, that it acted maliciously." In reversing the judgment founded on the verdict for the defendant, this court held that, "Corporations are liable like individuals for injuries done, although the act was not beyond their lawful powers." The grounds of the decision are stated in the opinion by Lane, C. J., as follows: "That the rights of one should be so used as not to impair the rights of another, is a principle of morals which, from very remote ages, has been recognized as a maxim of law. If an individual, exercising his lawful powers, commit an injury, the action on the case is the familiar remedy; if a corporation, acting within the scope of its authority, should work wrong to another, the same principle of ethics demands of them to repair it, and no reason occurs to the court why the same remedy should not be applied to compel justice from them." That decision is founded upon the broad principles of common justice and constitutional right. It is applicable to, and decisive of, this case.

No argument can be required to prove that, if the plaintiff's riparian rights are property for which, when injured by an individual, the latter may be held liable therefor in an action, they are none the less property when so injured or taken by the public; nor that those acts which, when done by an individual constitute a deprivation of the owner of his property, are equally so when done for the benefit of an aggregation of individuals that go to make up the population of a municipal corporation. Nor can it add anything to the defendant's prerogatives, nor take anything from the plaintiff's rights, to call the injury he has suffered consequential. The owner is nevertheless deprived of substantial property interests, and no name by which the acts that produce that effect may be called can destroy or diminish his constitutional right to indemnity.

The question whether the injury constitutes a taking of property depends upon its effect on the owner's proprietary rights, and not upon the length of time necessary to produce that effect. They may be as effectually taken by continuing acts extending over a considerable period of time as by a single act.

The case of Rhodes v. City of Cleveland, supra, has been repeatedly approved and followed in subsequent decisions of this court. In McCombs v. Town Council of Akron, 15 Ohio, 474, 479, Read, J., after stating that "the sole question in this case is whether a municipal corporation can be made liable for an injury resulting to the property of another, by an act of such corporation, strictly within the scope of its corporate authority, and unattended by any circumstance of negligence or malice," with his usual clearness and force, says: "The case of Rhodes v. City of Cleveland, 10 Ohio, 159, 36 Am. Dec. 82, with admirable good sense and strength of reason, answers this question by asserting that corporations are liable, like individuals, for injuries, although the act was not beyond their lawful powers. The late learned Chief Justice Lane, who pronounced the opinion of the court in that instance, accounts for the older cases upon the ground that courts were hampered by the mystic notion attached to corporate seals, by which corporations withdrew themselves from responsibility, and cast it upon their agents. A sort of transcendentalism which enveloped both the courts and the profession in a mist growing out of the airy nothingness of the subject-matter enabled corporations, like the pestilence which walketh unseen, to do their mischief and escape the responsibility. It is refreshing to the jurist, and important to the rights of individuals, that these confused notions are yielding to a clearer light and more solid reason." The learned judge further said: "We recognize the doctrine of that case, as laid down by this court, as founded in the most solid reason, right and morals, and a majority of the court have not the slightest disposition to impair its obligation, but by the light of such example and assurance, hope that the whole subject-matter of corporations will, in the end, be reduced to the control of incontestable principle." In City of Dayton v. Pease, 4 Ohio St. 80, 94, speaking of both of the above cases, Ranney, J., said: "In each of those cases, the liability of a municipal corporation, acting through subordinate agents, within the scope of its authority, and without malice or negligence, was enforced, where the acts of such agents resulted in injury to the property of private individuals. The propriety of investing such corporations with the power to improve their streets, resulting often in indirect injury to private property, is conceded; but the cases rest upon the clear principle of right and justice, which requires compensation to go hand in hand with public benefit. And when in the lawful exercise of these powers private property must be injured for the common benefit of all, all should be held liable to make reparation; and, in the view of the judges who concurred in these decisions, the principle was not without support from that section of the constitution of the State which secures the inviolability of private property."

We are satisfied, after the most careful consideration we have been able to give this case, that the judgments below are correct, and they are affirmed. (The judgments referred to awarded Balliett $400 damages.)

The Intermittent Sewage Filtration Plant at Clinton, Mass., produced a better effluent in 1901 than in 1900, according to the report of the Metropolitan Water and Sewerage Board. The sewage treated has been much more dilute than during the preceding year. The purification has in every respect been better during the last half of the year than during the first. The percentages of oxygen consumed and albuminoid ammonia removed from January to June were 87 and 87, and from July to December 95 and 96 respectively. The free ammonia removed from January to June was 70 per cent. and from July to December was 93 per cent. The nitrogen as nitrates in the effluent was, in parts 100,000 from January to June, 0.5383, and from July to December, 1.3213. The cost per million gallons filtered during the year was $8.29.

The Glendive Highway Bridge.

The highway bridge across the Yellowstone River at Glendive, Dawson County, Montana, is about 1,237½ feet long and has four through pin-connected fixed-truss spans of about equal length, the longest two being 311 feet 2 inches center to center of piers. It replaces an older structure built on the same axis and with piers in nearly the same position. The old piers were all pairs of steel cylinders sunk a few feet below the river bottom and filled with concrete, except one circular pier which supported a draw span about 325 feet long over all. Three of the old channel piers were removed and those at the ends of the bridge were retained for abutments for the new superstructure. The channel piers were replaced by long and narrow concrete piers about 45 feet high; a pair of old pier cylinders on an island were retained and built up with a special riveted steel superstructure to the same level as the tops of the new piers and steel extensions were seated on the abutment piers and braced to small new piers on shore to support the ends of the end spans. The old span at the west end of the bridge was retained and was raised about 7 feet above its original position and the other three spans were built new.

At the west end of the bridge the concrete in the old cylinder piers was excavated to a depth of about 2 feet and 18 inches of fresh concrete filled in and a vertical post seated on it eccentric with the cylinder to correspond to the revised position of the span. Horizontal flange angles were riveted on all sides of the post at both top and bottom to receive the base and cap plates, which were stiffened by short vertical diaphragm channels riveted into the ends of the post with their ends milled to bearing on the plates. The cap plate was planed and had two guide angles on the sides to engage the ends of the roller frame under the expansion end of the truss. The posts were connected by top and bottom lateral struts and X-bracing in the transverse plane. The bent thus formed was braced longitudinally by vertical triangular trusses with their bottom chords connected to the tops of the columns in a second transverse bent seated on new concrete piers 3 feet in diameter, which were built in steel cylinders sunk on shore. These trusses were connected by stiff bracing in the inclined and horizontal planes of the top and bottom chords, and rigidly connected the two bents. The bottom of the shore bent was anchored to bolts built into the concrete and was adjustable for height by loose T-shaped filler plates with their edges trimmed to pass between the anchor bolts and permit them to be inserted between the pier top and column base.

At the east end of the bridge the old cylinder piers were extended to new grade in a similar manner but with a difference of detail in the columns and bracing. The columns were about 9 feet long over all, and had no caps but were bored to receive the end lower chord pins of the main bridge trusses. The longitudinal bracing trusses were made entirely of 12-inch channels, field-riveted together with double gusset plates on the flanges. The trusses were braced similarly to those at the west end, but their shore ends had shoe plates seated directly on top of the new concrete piers and anchor-bolted to them in the same way, with adjustable packing plates without the interposition of a vertical bent.

The old pier on the island was built up by vertical columns made with iron channels and two wide cover plates in longitudinal planes. They are connected by horizontal top and bottom struts and X-bracing in the transverse vertical plane and have extended base plates seated on new concrete in the tops of the cylinders to which they are field-riveted through bent angles. After the columns were set in the pier cylinders concrete was filled around the feet of the columns up to the edges of the shells and rounded up to make a finished upper surface.

Mr. C. F. Loweth was the chief engineer for the reconstruction of the bridge and designed the substructure and superstructure.

Personal and Obituary Notes.

A. M. Carter, city engineer of Fargo, N. D., died August 4 after a severe attack of pneumonia.

The Coahuila & Pacific Railroad was formally opened August 11. Under the reorganization announced at that time, Mr. T. S. Abbott remains as chief engineer, at Saltillo, Mex.

Mr. P. D. Fitzpatrick has tendered his resignation as assistant chief engineer of the Illinois Central Railroad to become superintendent of concrete work and arches for the Katterjohn Construction Co.

Mr. F. F. Vandevort has resigned his position as general manager of the Chester Iron & Steel Works, of Chester, Pa., and Mr. Walter B. Ferrier, of the Carnegie Steel Works, has been elected to succeed him.

Francis Newberry Holbrook, M. Inst. M. E., died at his home in New York City, August 12, of brain fever. He was born fifty years ago in Connecticut and was graduated from the School of Mines of Columbia University.

Mr. George F. Sever, M. Am. Inst. E. E., adjunct professor of electrical engineering at Columbia University, has been appointed consulting electrical engineer to the Department of Water Supply, Gas and Electricity of New York City.

Mr. William E. Dickey, late past assistant engineer, U. S. N., announces that after August 25 he will represent The Goulds Manufacturing Co., of Seneca Falls, N. Y., and The West Point Boiler Works, of Pittsburg, at 16 Murray St., New York.

Lorenzo Russell Clapp, M. Am. Soc. C. E., died suddenly in Brooklyn, August 13, of apoplexy, at the age of 60 years. He was identified chiefly with sewerage and water-works construction in Brooklyn, where he was with the city engineering department for fifteen years. During the civil war, he served in the United States Navy.

In the death of Joseph Bond, president of the American Radiator Co., Chicago lost one of her prominent business men and useful citizens. He was born at Ware, Mass., in 1852, and was a descendant of one of the oldest families of the Bay State. He was educated in public and private schools, and at the age of eighteen entered business life. From 1875 until 1880 he was engaged in the hardware trade at Waltham, Mass. He removed to Buffalo a year later, and became connected with a firm manufacturing heating appliances. He was soon made treasurer of the concern, and that position he held until 1892, when he went to Chicago to assume executive control of the then newly organized American Radiator Co. The growth and prosperity of this concern are largely due to Mr. Bond's tireless industry, his thorough knowledge of the technical side of the business, and his unusual organizing ability. Under his direction the company steadily extended its operations and scope, employing 3,500 men and having factories and branches in several cities in the United States, and in England, Germany and France. Mr. Bond made a science and an art of his work, exhaustively studying the principles of manufacturing steam and hot water heating materials, and introducing new methods into that special industry. He was prevented by his close application to business from taking that part in public affairs for which his intelligence and integrity conspicuously fitted him, but he was a keen observer and an interested student of political, economic and social questions. He was a trustee of the Chicago University and took a deep interest in its progress.

The Removal of Soil at the site of the Wachusett Reservoir is the subject of numerous statistics in the report of the Metropolitan Water and Sewerage Board. The total amount of soil removed and to be removed is estimated to be about 6,900,000 cubic yards, from approximately 4,200 acres. Of this, the total amount removed from the reservoir in previous years was 2,278,723 cubic yards, from 1,358 acres; in 1901, 1,309,925 cubic yards were removed, from 758 acres; making a total from the beginning of work to the end of 1901 of 3,588,648 cubic yards, or 52 per cent. of the total. The plant employed in this work toward the end of the season, exclusive of horses and carts, included 27.3 miles of 3-foot-gauge track, 25 8 to 16-ton locomotives, 720 cars of 1¾ to 3½ cubic yards' capacity, a 70-horse-power hoisting engine and a 50-horse-power hoisting engine.

The Working of the Intermittent Sewage Filtration Plant at Brockton, Mass., is described in the annual report for 1901 of the City Engineer, Mr. Charles R. Felton. The work accomplished by the filter-beds, based on the quantity of sewage purified and its strength as represented by the albuminoid ammonia, has been 43 per cent. more in 1901 than in 1900, and five times as great as that accomplished in 1896. The sludge raked from the beds has been sold to farmers for fertilizer, $150 being received for the year's product. Three acres of the filtration area planted with yellow corn yielded a net profit of $45.36. One acre was planted with sunflowers, and about 33 bushels of seed were secured and disposed of at a slight profit. The surface sand of several of the beds has become discolored, owing to the large amounts of waste blacking discharged into the sewers from the shoe factories. This, however, does not impair the efficiency of the beds in any way. Analyses of the effluents from the three drains gave as the average percentage of albuminoid ammonia removed from the sewage 98.1, 98.8, and 98.7.

The New Garbage Crematory of Winnipeg, Man., is described as follows in the 1901 report of the City Engineer, Mr. H. N. Ruttan: The crematory consists of 4 cells, connected with a chimney 3½ feet square and 80 feet high. Each cell is provided with a coal grate and garbage grate, the coal grate being at the front of the cell and lower than the garbage grate. The material to be burnt is dumped onto the garbage grate through an opening in the top of the furnace above it. This opening is large enough to take in horses. As the garbage is consumed, that behind is gradually drawn forward onto the coal fire. At the entrance of the smoke flue to the chimney is a fire to consume fumes and gases from the burning garbage. The crematory is enclosed by a suitable frame building, with wagon approaches to the top of the furnaces, constructed by the Works Department at a cost of $3,755.34. This includes sewers, catch-basins and other contingencies. The contract price of the work, done by the Toronto Furnace & Crematory Company under the supervision of this department, is $10,290.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvi, xvii, xviii and xxvii.

WATER.

Lecompte, La.—This village has voted to install water works at a cost of $8,000. Ira W. Sylvester, of Alexandria, La., Consulting Engr.

Salt Lake City, Utah.—S. B. Milner, Pres. of the Twin Falls Land & Water Co., writes that the irrigation system which it is proposed to build will cost about $1,600,000.

Charleston, W. Va.—City Recorder W. W. Wertz writes that plans are being made for municipal ownership of the waterworks. Estimated cost $175,000 to $250,000. Address, A. D. Mead, Councilman.

Grinnell, Ia.—Bids are wanted Aug. 22 for the construction of a dam, to be approximately 400 ft. long, 22 ft. high and 16 ft. wide on top, as advertised in The Engineering Record.

Kansas City, Mo.—Bids are wanted Sept. 1 for furnishing and erecting complete on foundations provided by the city, 1 vertical triple expansion condensing crank and flywheel pumping engine of 15,000,000 gal. capacity in 24 hours, against an average head of 145 lbs. Hydrostatic pressure; steam pressure at throttle, 155 lbs. Baxter Brown, Secy. Bd. of Pub. Wks.

Wilmont, Minn.—Engr. in Charge M. B. Haynes, of Mankato, writes that the following bids opened Aug. 5 for the construction of water works were all rejected: Allan Black & Co., St. Paul, $6,980; W. D. Lovell, Des Moines, Ia., $6,790; Des Moines Iron & Bridge Co., Des Moines, $7,036.

Lidgerwood, N. Dak.—City Aud. John Nuding writes that J. J. Flather, University of Minnesota, Minneapolis, is the engineer in charge of proposed water works construction, estimated to cost $8,000.

South Deerfield, Mass.—Water Comr. J. B. Bridges writes that contracts will be let after Sept. 1 for the construction of water works, estimated to cost $30,000. Engrs. in Charge, Clapp & Abercrombie.

New Windsor, Colo.—C. F. Finley, of the Poudre Valley Reservoir Co., writes that the contract for constructing a ditch and reservoir has been awarded to J. A. Banning, 1417 Bway., Denver, for about $200,000.

Beaumont, Tex.—The Riceland Irrigation Co., of Beaumont, has been incorporated, with a capital of $150,000, its purpose being to construct, maintain and operate lakes, reservoirs, etc., for irrigation, mining, etc. Incorporators: A. Oswald and Roscoe L. Oswald, of Jefferson County, Tex.; C. A. Walker and others, of Jackson County, Tex.

Abingdon, Ill.—The City Clk. writes that water mains are to be laid at a cost of $2,800. Geo. C. Morgan, of Chicago, Engr. in Charge.

Charleston, S. C.—The American Pipe Mfg. Co., Philadelphia, Pa., has extended the time for receiving bids for the construction of a dam and reservoir at Charleston, until Aug. 25, as advertised in The Engineering Record.

Portsmouth, O.—Bids are wanted Sept. 2 for all material and labor for installing an intake crib, to be located in Ohio River, together with necessary suction pipe, etc., as advertised in The Engineering Record.

Ithaca, N. Y.—Bids are wanted by the Ithaca Water Works Co. until Sept. 1 for building a concrete dam in Six Mile Creek, as advertised in The Engineering Record.

Joliet, Ill.—Bids are wanted Aug. 25 for constructing a 1,000,000-gal. storage reservoir. H. A. Stevens, City Engr.

Mendota, Ill.—Mayor E. S. Browne writes that the city proposes to construct water works at a cost of $15,000. The contract is practically let for 2 120-H.-P. boilers, but bids will be received Sept. 1 for a 100-ft. circular brick stack and brick building. F. H. Hamilton, Engr. in Charge, Springfield, Ill.

Marietta, O.—Local press reports state that City Engr. E. Frank Gates is preparing plans for a reservoir.

Philadelphia, Pa.—Local press reports state that the lowest bid received by the Dept. of Pub. Wks. on Aug. 12 for building the proposed new pumping station at Lardner's Point was from Geo. C. Dietrich at $725,000; time for completion, 250 days.

Columbus, Ga.—An ordinance before the City Council provides for a vote on the proposition to issue $250,000 bonds for the construction of a municipal system of water works.

Henry, Ill.—Mayor A. G. Humphrey writes that none of the bids received Aug. 10 for the construction of a system of water works were accepted. Action has been postponed until Aug. 21; specifications will be changed and new bids asked.

Allegheny, Pa.—D. L. Fulton, Dir. Dept. of Pub. Wks., writes that the contract for erecting an addition to Howard St. pumping station has been awarded to H. A. Kunze, 14 E. Diamond St., for $20,490.

Chester, Ill.—The City Council is reported to have granted a franchise to the Chester Light, Water & Ice Co. for the laying of water mains.

Saginaw, Mich.—An appropriation of $500 has been made for the purpose of making tests of the proposed pure water supply from a chain of wells.

Los Angeles, Cal.—Bids are wanted Sept. 8 for the following cast-iron water pipe and specials: 6,975 pieces of 4 to 36 in. pipe, weighing from 20 to 400 lbs. per ft. and 60 short tons of specials to be used with pipe. Wm. Mulholland, Supt. of Water Wks.

Minneapolis, Minn.—The Council on Aug. 8 adopted a resolution providing for the issue of $250,000 bonds for the purpose of improving the water supply of the city.

Goshen, Utah.—The Goshen Irrigation & Canal Co. has filed articles of incorporation. Capital, $100,000. The officers are: Hans Jasperson, Pres.; Geo. White, Vice-Pres.; John Jasperson, Sec. and Treas.

Sault Ste. Marie, Mich.—Press reports state that $125,000 water, $40,000 sewer and $35,000 street bonds have been sold.

New Brighton, Pa.—The Citizens' Improv. Asso. has taken steps to build a municipal water works.

Blue Ridge, Ga.—See "Sewerage and Sewage Disposal."

Memphis, Tenn.—Consulting Engrs. J. A. Omberg, Jr., Arthur Hider and A. T. Bell, employed by the city to report upon the water works of Memphis, have submitted their reports, in which estimates are given as follows: To duplicate present plant, $2,402,164; auxiliary plant (compressed air), $292,000; auxiliary plant (steam), $225,125; independent station, $856,750; Mississippi River plant, $2,461,000; extending mains to Riverside Park, $105,542; service connections and meters, $304,332; to meet insurance requirements, $269,586; depreciation of present plant, $386,270; value present plant (not including real estate), $2,015,894.

Wausa, Neb.—The matter of establishing a water system is said to be under consideration.

Austin, Tex.—The City Council on Aug. 4 voted to purchase the plant of the old water company for $175,000.

Oakland, Cal.—The City Council has passed an ordinance appropriating $40,000 for the immediate improvement of 12th St. dam.

North Plainfield, N. J.—Boro. Clk. Frank Rowley writes that on Aug. 12 it was voted to issue $10,000 fire protection bonds.

Lancaster, Pa.—The Special Water Com. has decided to ask Samuel M. Gray, of Providence, R. I., to visit this city and explain his recommendations for a new standpipe and a duplicate force main.

Toledo, O.—Members of the Water Works Bd., with Supt. T. R. Cook, have visited the sand filtration plants in other cities with a view to installing a similar plant at Toledo.

New London, Wis.—Bids are wanted by the Mayor and City Council until Aug. 28 for furnishing material, f. o. b. cars, for a water works plant, as advertised in The Engineering Record.

Zelienople, Pa.—Bids are wanted Aug. 21 for furnishing material and constructing a system of water works, as advertised in The Engineering Record.

San Antonio, Tex.—The San Antonio Water Works Co. is reported to have made an appropriation of $227,000 for improvements, including the erection of a pump house 25x72 ft. on Market St., the drilling of 5 12-in. artesian wells and the installation of a 10,000,000-gal. pump and a 15,000,000-gal. pump. The contract for drilling the wells has been let to Judson Bros. Geo. W. Brackenridge, Pres. of Co.

Aberdeen, Wash.—At the recent election bonds to the amount of $100,000 were voted for refunding the present municipal indebtedness, the improvement of the water works system, constructing a modern sewerage system and building a bridge across Chehalis River.

San Francisco, Cal.—City Engr. C. E. Grunsky has submitted to the Bd. of Pub. Wks. his report on the city's water supply. Tuolumne River is reported to be the most feasible source of supply, and estimates given were as follows: Cost of bringing a supply of 60,000,000 gal. of water per day to the city, $30,724,000; distributing system to cost $1,057,000; city pumping station, $5,318,560, with pipe laying, gates, tunnels, etc., making a total of $39,531,000. Estimated cost of maintenance, $585,200 per year.

Portsmouth, N. H.—The Bd. of Aldermen is stated to have passed an ordinance for the issue of $50,000 bonds for the construction of an additional water plant, supply to be taken from Peverly Brook in Newington.

Vernal, Utah.—The Ashley Valley Irrigation & Reservoir Co. has been incorporated, with a capital of $50,000.

Pittsburg, Pa.—C. E. Holland, of New York, Capt. J. M. Murphy, of Harrisburg, and others, are said to be forming a new company, with a capital of $10,000,000, to supply Pittsburg and vicinity with pure water.

El Paso, Tex.—Jonathan S. Dodge and associates have asked the City Council for a 40-year franchise for a water works system, with permission to acquire the old plant.

Denver, Colo.—The Water Co. has taken out permits with the Bd. of Pub. Wks. for the laying of over 3 miles of water mains.

Schulenburg, Tex.—The Attorney General has approved an issue of $11,000 city water works bonds.

Coopersburg, Pa.—This Boro. has voted to borrow $19,000 for municipal water works.

Waco, Tex.—The City Council on Aug. 7 passed an ordinance providing for the issue of $200,000 bonds for the construction or purchase of a water works plant.

Rockwall, Tex.—The Attorney General has approved an issue of $12,000 city water works bonds.

Menno, S. D.—Bonds to the amount of $4,000 were voted for a system of water works.

Columbus, O.—The contract for furnishing not more than 1,400 or less than 800 tons of water pipe has been awarded by the Bd. of Pub. Wks. to the U. S. Cast Iron Pipe & Fdy. Co. at its bid of $33.50 per ton.

Hempstead, L. I., N. Y.—The Town Bd. has passed a resolution requesting the Jamaica Water Supply Co. to furnish 15 additional hydrants in the Floral Park Water Supply Dist.

Winnipeg, Man.—The Water & Light Comr. recommends the construction of a storage reservoir having a capacity of 10,000,000 gal.

Campbellsville, Ky.—Press reports state that the City Council is receiving bids for water works and an electric light plant.

Mullica Hill, N. J.—The Mullica Hill Water Co., principal office, Mullica Hill, has been incorporated, with a capital stock of $25,000. Incorporators: Eugene N. Howell, J. W. Howell, Fred. Blackburn and others.

Penngrove, N. J.—The Boro. Council has approved plans and specifications for the water works and electric light plant, for which $35,000 bonds were recently voted.

Georgetown, Del.—The Sussex Water Co. has been incorporated, with a capital of $25,000, to establish, maintain and operate water and light plants in Georgetown and other Sussex Co. towns. Chas. W. Cullen, of Georgetown, is said to represent the Co.

Whitesboro, Tex.—This city will grant a franchise for water works. An artesian water supply can be had at a depth of 400 to 800 ft. Population, 2,000. Address, O. T. Cartwright, City Secy.

Greenville, Pa.—The water works of this place have been purchased by Ernest Acheson, of Washington, Pa.; J. N. Clark, of Washington, and others, for approximately $60,000. It is stated that $20,000 will be expended in improving and extending the plant.

St. Louis, Mo.—The Malvern Water & Improv. Co., of St. Louis, has been incorporated to establish and operate water, sewer and lighting systems. Capital stock, $5,000. Incorporators: Chas. W. Smith, Alfred W. Syrett, Jas. J. McDonald and others.

Quanah, Tex.—The Attorney General has approved the issue of $8,000 water works bonds.

Tabor, Ia.—This place is reported to have voted $6,000 bonds for water works.

Conrad, Ia.—It is stated that water works are to be built.

Concord, N. C.—This city has decided to expend about $70,000 for the construction of water works. J. L. Ludlow, of Winston, N. C., is said to be Engr. in Charge.

Philadelphia, Pa.—Local press reports state that bids for building the fire-main pumping station to be located at the foot of Race St. will be asked soon.

North Milwaukee, Wis.—Village Clk. W. E. Chase writes that on Aug. 12 it was voted to issue $30,000 bonds for water works improvements.

Orillia, Ont.—Town Treas. C. E. Grant writes that on July 31 it was voted to issue $18,000 bonds for water works improvements and $30,000 bonds for an electric light plant.

Stuttgart, Ark.—The Stuttgart Water & Electric Light Co. has filed a certificate increasing its capital stock from $10,000 to $50,000. Chas. Williamson is Pres. of the company, Emil Reinsch, Vice-Pres., and A. W. Harper, Secy.

Chicago, Ill.—Local press reports state that the Bd. of Trus. of the Sanitary Dist. of Chicago will receive bids about Oct. 15 for constructing a dam for preserving the Joliet water power and to build an extension to the main channel at Lockport. The latter work, it is stated, will involve excavating and building of concrete walls on each side of the canal for about 7,000 ft. south of the bear-trap dam.

City Engr. Ericson estimates the cost of installing the new high-pressure fire protection system downtown at $567,250.

Local press reports state that contracts will soon be let for 3 pumps, each having a daily capacity of 2,500,000 gal., to be installed at the Chicago Ave. Pumping Station. Estimated cost, $350,000.

New York, N. Y.—Bids were opened Aug. 7 by Robt. G. Monroe, Water Comr., for furnishing and laying water mains in various streets. Some of the largest items and prices of lowest bidder are as follows: 2,900 tons straight pipe at $31, 70 tons branches at $56, 3,300 cu. yds. rock excavation at $.25, 40,000 cu. yds. earth excavation at $.25, 40,000 cu. yds. filling at $.25, laying 17,000 ft. of 20-inch pipe at $.51, laying 13,500 ft. of 12-inch pipe at $.27, laying 45,000 ft. of 6 inch pipe at $.16. The bidders and the totals are as follows: Contract awarded to H. Lipps, Jr., $152,117.30; F. V. Smith Cons. Co., $174,855; Norton & Dalton, $165,141; Cunningham & Kearns, $166,456; F. Thilemann, Jr., $178,997.50.

Columbus, O.—Julian Griggs, Ch. Engr., Dept. of Pub. Improvements, writes that the following bids were opened Aug. 8 for constructing a concrete masonry dam: A, Chas. Louis Cornwell, Louisville, Ky., total exclusive of cement, $184,678 with lake sand (awarded); $177,934 with river sand; B, S. Casparis, Jns. Westwater & Co., Columbus, total exclusive of cement, $190,250; total including cement, $302,650; C, A. W. McDonald & Co., Steubenville, O., total exclusive of cement, $207,074; total including cement, $347,574. For detail bids of above bidders see accompanying table:

Items and Quantities.

	A	B	C
Earth excav.:			
Dry, in found., 7,000 cu. yds.....	$.50	$.60	$.35
Wet, in found., 6,000 cu. yds.....	1.25	1.50	.85
Rock excav. in found., 15,000 c. yds.	1.50	1.50	1.05
Concrete masonry:			
56,200 cu. yds., lake sand........	2.69	2.75	3.27
56,200 cu. yds., river sand.......	2.57	....	....
56,200 cu. yds., including cement..	....	4.75	5.77

Bids received on Portland cement, 56,200 bbls., were as follows: Columbus Macadam Co., Columbus, for "Giant," $2.13 in bbls., $2.28 (awarded) in cloth, $1.98 in paper; totals, $119,706, $128,136 and $111,276, respectively; Kelly Island Lime & Transport Co., Cleveland, on "Lehigh," $2.21 in bbls., $1.94 in cloth, and $2.04 in paper; totals, $124,202, $109,028 and $114,648, respectively. Other bids received for Portland cement were as follows: *a*, 40,000 bbls.; *b*, 4,000 bbls.; *c*, 20,000 bbls.: J. P. Carlisle, Columbus, *a* on "Diamond," $2.35, total $94,000; *b* on "Medusa," $2.38 in cloth or $2.40 in paper, totals $9,400 and $9,600, respectively; A. Hamilton and E. W. Parker, Columbus, O., *c* on "Alpha," $2.75 in bbls. or $2.50 in cloth, totals $55,000 and $50,000, respectively.

Lewiston, Idaho.—City Engr. Ernest McCullough writes that the following bids were opened July 24: *a*, for a pump capable of lifting 1,000,000 gal. in 24 hours against a head of 220 ft.; *b*, for one with 50 per cent. more capacity; *c*, for a 125-H.-P. boiler: Laidlaw-Dunn-Gordon Co., *b* \$2,600, *a* \$2,200 f. o. b. Cincinnati. W. D. Hofius & Co., Seattle, Wash., offered three second-hand Worthington steam pumps capable of raising 1,500,000 gal. 600 ft. in 24 hours for \$2,500 each f. o. b. Seattle. Dean Steam Pump Co., Holyoke, Mass., *b* \$2,295, *a* \$2,098 f. o. b. Lewiston. Bradley Engineering Co., Spokane, Wash., representing Stillwell-Bierce & Smith-Vaile Co., offered f. o. b. Dayton, O., *a* \$1,210 with following extras: Lagging steam cylinder, \$50; revolution counter, \$50; 3 gauges, \$55; surface condenser, \$385; vertical air pump, \$455; *b* \$1,455 with following extras: Lagging steam cylinder, \$50; revolution counter, \$50; 3 gauges, \$55; surface condenser, \$575; vertical air pump, \$455. Canton Steam Pump Co., Plain duplex pump, \$500; compound duplex steam pump, \$700 f. o. b. Canton, O. A. V. Kniser & Co., Philadelphia, offered 2 second-hand Worthingtons, capacity 3,000,000 gal., at \$5,500 each f. o. b. Philadelphia, Pa. D'Olier Engineering Co., Philadelphia, \$4,200 for De Laval Steam Turbine f. o. b. Lewiston. Henry R. Worthington, f. o. b. Lewiston, *a* \$2,130, *b* \$2,560. Bradley Engineering Co., *c* f. o. b. Dayton, O., horizontal return tubular, \$925. New Jersey Fdy. & Mch. Co., *c* f. o. b. Lewiston, \$1,560.

Power pumping propositions were as follows: Deane Steam Pump Co., power pump for \$1,600, with a 60 H.-P. motor, for \$1,158, and a 95 H.-P. motor for \$2,218, electric motors. Westinghouse Electric & Mfg. Co., Seattle, Wash., power pump for 1,500,000 gal., \$3,000, with electric motor, \$3,212; total, \$6,212; 1,000,000-gal. pump, \$2,000, and motor \$2,500; total \$4,500; for a 2,500,000-gal. pump, \$5,500, and motor, \$3,937; total, \$9,437, all to be f. o. b. factory. Bradley Engineering Co., Spokane, Wash., f. o. b. Dayton, O., power pumps, \$1,750 and \$2,290, but no figures on motors.

SEWERAGE AND SEWAGE DISPOSAL.

West Carthage, N. Y.—Bids are wanted Aug. 30 for the construction of a sewer system, as advertised in The Engineering Record.

Wapakoneta, O.—Bids are wanted Aug. 25 for furnishing necessary labor and material for improving Blackhoof St. by the construction of a sewer with all appurtenances. Chas. E. Fisher, Village Engr.

Kansas City Mo.—Ordinances have been passed, and in a short time contracts will be let, for the following sewer construction: Sewer Dist. No. 208, which includes 13,500 ft. of pipe and 2,127 ft. of brick sewers, 55 manholes, 45 catchbasins and 7 flush tanks, cost \$30,000; also Sewer Dist. 221, which includes 18,000 ft. of pipe and 3,500 ft. of brick sewers, 69 manholes, 62 catchbasins and 7 flush tanks, cost \$36,000. R. W. Waddell, City Engr.

New York, N. Y.—Bids are wanted Aug. 19 for furnishing material and making alterations to a sewer in 51st St., between Park and 5th Aves. Engr.'s estimate of the work is as follows: 760 lin. ft. of 3-ft 6-in.x2-ft. 4-in. brick sewer, Class 1, and 30 lin. ft. of 3-ft. 6-in.x2-ft. 4-in. brick sewer, Class II; 36 lin. ft. of 12-in. salt glazed vitrified stoneware pipe culvert, etc. Geo. Livingston, Comr. of Pub. Wks.

Santa Rosa, Cal.—J. W. Keegan, Chmn. Sewer Com., writes that the sewer system is to be extended, at a cost of \$4,000.

Ft. Dodge, Ia.—Press reports state that bids are wanted for the construction of an 18-in. storm water sewer.

South Bend, Ind.—Press reports state that preparations are being made to reclaim the Kankakee marsh, southwest of the city, by the construction of a drainage canal which will be 17 miles in length and cost about \$85,000.

Mission Valley, Ia.—Local press reports state that Harrison and Pottawattamie Counties have decided on plans for a system of canals which will drain 100,000 acres of land in Ia.

Duquesne, Pa.—Boro. Engr. S. A. Taylor, of Pittsburg, writes that the contract for constructing 4,600 ft. of 8 to 12-in. pipe sewers, with 13 manholes, 6 catchbasins and 4 flush tanks, has been awarded to Homan & Cardwell, of Duquesne, at 84 cts. to \$1.10 for 12-in. pipe, 64 cts. for 10-in. pipe, 58 cts. to \$1.90 for 8-in. pipe, 42 cts. to 60 cts. for 6-in. connections, \$30 and \$38 for manholes, \$60 and \$65 for flush tanks; total, \$7,291.

West Point, N. Y.—Major J. B. Bellinger, Q. M., U. S. M. A., writes that the contract for 348 ft. of 20-in. cast iron pipe laid, has been awarded to E. A. Matthews, 13 Park Row, New York City, at \$14.25 per lin. ft.

Portsmouth, O.—City Engr. B. C. Bratt writes that the contract for sewer construction (bids opened Aug. 5) has been awarded to Samuel Monroe & Son, of Portsmouth, at \$1.55 per ft. for 30-in. brick sewer. 542 ft. 16.8 cts. for excavation; total, \$3,858.

Belleville, Ill.—The City Council has passed an ordinance for the construction of a brick sewer, 30-in. and 36-in. Cost about \$15,000. Louis Graner, City Engr.

Danville, Ill.—City Engr. W. H. Martin writes that bids are wanted Aug. 21 for 3,000 ft. of 8-in. pipe sewer.

South Bend, Ind.—See "Paving and Roadmaking."

Mobile, Ala.—Bids are wanted Aug. 28 for constructing storm sewers, as advertised in The Engineering Record.

Atlantic, Ia.—The City Clk. writes that the Iowa Engineering Co. has been engaged to prepare plans and specifications for a sewerage system which is to be started next year.

New Brighton, S. I., N. Y.—Bids are wanted Aug. 22 for the construction of a storm water sewer, with appurtenances, in Amos St.; the engineer's estimate calls for 1,035 ft. of 2-ft. 2-in.x3-ft. 3-in. brick sewer, 445 ft. 2-ft. 6-in.x3-ft. 9-in. and 100 ft. 3-ft. 6-in. lt diameter brick sewers; 12 manholes, etc. Bids are also wanted for constructing pipe sewers in Hamilton and Hatfield Aves. Geo. Cromwell, Pres. Boro. of Richmond.

Grinnell, Ia.—Engr. in Charge A. Marston, of Ames, Ia., writes that the contract for constructing septic tank of 250,000-gal. capacity has been awarded to O. P. Herrick, of Des Moines, Ia., for \$7,239. Other bidders were Des Moines Bridge & Iron Co., \$7,324; M. V. Kenned, Des Moines, \$7,949; Donnegan & Sullivan, Shenandoah, \$8,200.

Lakewood, O.—Bids are wanted Sept. 6 for laying the necessary sewer and water mains on Lake Ave. Bids will also be received by the Bd. of Hamlet Trus. in Sept. for laying necessary sewers on Clifton Boulevard. Plans may be obtained at the office of The Wm. H. Evers Engineering Co., Williamson Bldg., Cleveland. John French, Hamlet Clk.

Camden, N. J.—Local press reports state that the Street Com. of the City Council will receive bids Aug. 19 for the construction of several sewers.

Bridgeport, Conn.—Bids are wanted Aug. 20 for the construction of about 1,200 ft. of 40-in. brick sewer, as advertised in The Engineering Record.

Montreal, Que.—Bids are wanted Aug. 21 for constructing sewers in portions of Belanger and Cowan Sts. John R. Barlow, City Surveyor.

Ridley Park, Pa.—Bids are wanted Oct. 10 for a complete sewage disposal and purification plant, as advertised in The Engineering Record.

Blue Ridge, Ga.—City Clk. J. H. Davis writes that the estimated cost of proposed water works and sewerage system is \$15,000.

South Bend, Ind.—The Bd. of Pub. Wks. has passed resolutions for the construction of pipe sewers on East La Salle St. and a portion of Franklin St.

Port Huron, Mich.—Press reports state that the Council has under consideration the issue of \$60,000 sewer bonds.

Sault Ste. Marie, Mich.—See "Water."

Devils Lake, N. D.—The City Council is reported to have ordered the construction of a sewer system.

Revillo, S. D.—Surveys are said to have been completed for a complete system of sewerage.

Boston, Mass.—The time for receiving bids for furnishing and installing at the Calf Pasture, Dorchester, 6 boilers, is Aug. 25. Address Supt. of Streets.

Athol, Mass.—Bids are wanted by the Sewer Comrs. until Sept. 3 for constructing about 5 miles of sewers in this town, as advertised in The Engineering Record. Herbert L. Hapgood, Chmn.

Ogdensburg, N. Y.—The Common Council has voted in favor of constructing Barre St. sewer.

Boise, Idaho.—City Engr. Chas. H. Irvin writes that 2 lines of 6-in. pipe sewers, each 1,095 ft. in length, are to be constructed.

Oakland, Cal.—The Bd. of Superv. has directed the County Surveyor to prepare plans for macadamizing and constructing a sewer on San Leandro Road. Estimated cost, \$17,000.

St. Paul, Minn.—See "Paving and Roadmaking."

Torrington, Conn.—The contract for constructing sewers in numerous streets (bids opened Aug. 12) has been awarded to Ambrose Robbiati, 124 N. Elm St., Torrington, for \$10,392.

Peekskill, N. Y.—Sewer bonds to the amount of \$51,285 are reported to have been sold.

Pawtucket, R. I.—The Common Council has appropriated \$6,500 for the construction of new filter beds at South Woodlawn.

Durango, Colo.—H. T. Henderson has placed the estimated cost of a sewerage system at \$70,000.

Williamsport, Pa.—The Councils have awarded the contract for Building the Locust St. sewer conduit of brick, to Jos. Hendler Const. Co., of Wilkesbarre, for \$139,933.

Bradley Beach, N. J.—T. Frank Appleby, of Asbury Park, and others, have asked the Common Council for a franchise for the construction of a sewer system.

Guthrie, Okla. Ter.—The City Council has passed ordinances for 2 main sewers and for lateral sewers.

Aberdeen, Wash.—See "Water."

Swampscott, Mass.—The contract for Section 3 of the sewer system has been awarded to C. H. Eglee & Co., of Boston, for \$64,000.

Oak Cliff, Tex.—The Citizens' Sewerage Co., of Oak Cliff, has been incorporated, with a capital of \$6,000, to maintain a system of sewers. Incorporators: E. G. Patton, W. M. Ward and others.

Denver, Colo.—An ordinance has been passed authorizing the construction of sanitary sewers in South Side Sanitary Sewer Dist. No. 3, at a cost of \$16,800.

Westfield, Mass.—Town Engr. Oren E. Parks writes that the following bids were opened Aug. 6 for sewer construction. Trench to average 9.7 ft. in depth: A, Maloney & Peterson, Springfield, Mass., \$31,797 (awarded); B, Lynch Bros. Brick Co., Holyoke, \$35,610; C, R. D. Maynard, Springfield, \$37,763; D, Bruno, Salomone & Petitti, Boston, \$38,600; E, Seymour & Newell, Springfield, \$38,626; F, Long & Little, Leominster, \$39,087; G, D. H. Parsons & Co., Westfield, \$43,193; H, Brosman Bros., New York City, \$45,618. For detail bids see accompanying table:

Bidders.	Earth excav. 54-in. circular sewer, 4,610 ft.	36-in. circular sewer, 98 lin. ft.	Siphon, lump sum.	8-in. pipe sewer, 670 ft.	Br. masonry, 1,890 cu. yds.	Concrete mas., 725 cu. yds.	Spruce lumber, 15,000 ft. B. M.	Rock excav., 160 cu. yds.

POWER PLANTS, GAS AND ELECTRICITY.

New York, N. Y.—The Mayor has approved the issue of $200,000 bonds for the construction of a new heating and lighting plant for the American Museum of Natural History.

Jackson, Miss.—F. J. Butler, of Greenville, is stated to have secured the contract for constructing an electric power plant at the new Capitol, for $36,020.

Ladysmith, Wis.—The Council is stated to have granted the Ladysmith Light & Power Co. a 10-year electric light franchise. Work on the plant will begin at once.

Aberdeen, S. D.—Thos. Baker, Jr., and others, of Fargo, N. D., are reported to have petitioned for a franchise for an electric light and power plant.

Edwardsville, Ill.—The J. R. Bennet Electric Co., which is reported to have recently received a franchise for lighting this city, has purchased a site in the East End, near the Henrietta coal mine, where it is said its power plant will be located.

Boulder, Colo.—The City Council is stated to have awarded to the Boulder Electric Light & Power Co., whose contract for lighting the city does not expire until next May, a contract for 10 years from May 1, 1903, for lighting the city at the rate of $100 a year per arc light. It is stated that the company will expend about $40,000 in improvements.

Mercer, Pa.—L. W. Orr, Jas. D. Emery, and others, have asked for a franchise to construct an electric light plant.

Lancaster, Pa.—The Council has granted John L. Dunn & Co., of Wilkesbarre, to be known as the Lancaster Steam Htg. Co., a franchise to lay and maintain a system of pipes in Lancaster to supply private consumers with steam.

Knoxville, Tenn.—The Knoxville Water Power Co., which is reported to have been recently incorporated to dam the Little Tennessee River 30 miles above Knoxville, and generate power to supply electricity to the entire East Tennessee, has been organized, with Chas. H. Treat, Pres., and H. O. Reed, Secy., both of N. Y. City, N. Y.

Tiffin, O.—The Logan Natural Gas Co. is stated to have secured franchises in Tiffin and Carey.

Minneapolis, Minn.—It is stated that about $100,000 will be expended by the Minneapolis Electric Co. in improvements on the building at 15 8th St. S. Two stories will be added and storage batteries to increase the H.-P. to 4,000 will be put in.

Ft. Wayne, Ind.—The Ft. Wayne Electric Light & Power Co. has been incorporated, with a capital of $500,000, by Edw. R. Coffin, Wm. P. Bonbright and others. It is the intention of the company to supply electrical current, steam, hot water and gas to consumers in and near Ft. Wayne.

Anoka, Minn.—The City Council is stated to have granted J. W. Steed a franchise for an incandescent system.

Memphis, Tenn.—The Citizens' Gas & Electric Light Co. has been incorporated, with a capital of $100,000, by Dr. J. H. Stolper, Percy H. Patton, and others, for the establishment and operation of works for the manufacture, distribution and sale of gas and electric current for light, heat and power.

Baird, Cal.—The San Francisco Construction Co., San Francisco, and Geo. W. Elder, 455 Valencia St., San Francisco, are stated to have secured the contract for constructing a dam across McCloud River about 20 miles from Baird, for the McCloud River Electric Power Co.; probable cost, $500,000.

Sea Cliff, L. I., N. Y.—The Bd. of Trus. is stated to have granted a franchise for lighting Sea Cliff to the Roslyn Electric Light & Power Co.

Storm Lake, Ia.—A. W. Unger is stated to have petitioned the Council for a franchise for a gas plant.

Dansville, N. Y.—The Mill Creek Electric Light & Power Co. has been incorporated by F. A. Owens, W. J. Beecher, and others. It is stated that it is proposed to utilize the water of Big Mill Creek between Perkinsville and Dansville and erect and equip a plant to furnish Danville with electricity.

Orillia, Ont.—See "Water."

New Orleans, La.—Local press reports state that the City Council on Aug. 5 accepted the bid of Herbert A. Ballard, of Cincinnati, O., for the construction of the municipal electric light plant, for $1,369,000.

Tacoma, Wash.—City Engr. Norton L. Taylor writes that the following bids were opened July 30 for lighting the city for the next 5 years: *a*, price per Kw. hour for alternating current; *b*, price per Kw. hour for direct current: Tacoma Ry. & Power Co., Tacoma, *a* .895 cts., *b* .97 cts.; Tacoma Cataract Co., Tacoma, *a* .84 cts., *b* .94 cts. (awarded). Estimated consumption for year ending Aug., 1903, 3,200,000 Kw.

Campbellsville, Ky.—See "Water."

Fayetteville, N. C.—Bids are desired by this city on an electric light plant of 50 arc lights and 3,000 incandescent lights. N. B. Alexander, Chmn. Light Com.

Alton, Ill.—The Alton Electric Ry. Co. will extend its gas mains several miles. J. F. Porter, Pres.

Warrenton, Pa.—The Virginia Electrical Construction Co. is stated to have secured the contract for the installation of a $28,000 electric plant at Warrenton, Va., for the Warrenton Electric Co.

Charlotte, Mich.—The Council is reported to be investigating the advisability of installing an electric light plant in connection with the water works.

Pennsgrove, N. J.—See "Water."

Lancaster, N. Y.—The Lancaster-Depew Natural Gas Co. has been incorporated, with a capital of $100,000, to manufacture and produce gas for lighting purposes in Cheektowaga, Lancaster and Amherst. Directors: J. W. Stearns, of Akron; Frank D. Smith, of Springville, Lawrence P. Meyer, of Bowmansville, and others.

Georgetown, Del.—See "Water."

Emporia, Kan.—Contracts for machinery for the electric light plant are stated to have been awarded as follows: machinery, to the General Electric Co., Schenectady, N. Y., $12,240; boiler, to Fairbanks, Morse & Co., St. Paul, Minn., $2,475, and heater to the E. G. T. Colles Co., for $805.

Spokane, Wash.—The Stockholders of the Washington Water Power Co. are stated to have ratified an increase in the capital from $2,000,000 to $2,600,000. The increase is for improvements here and extending the power line into the Coeur d'Alenes. It is estimated that the total cost, including the line into Idaho, will be $475,000. T. B. Fisken, Supt., Spokane.

Charles City, Ia.—The citizens are stated to have voted Aug. 8 to grant a franchise to the Charles City Electric Light & Htg. Co.

Norfolk, Va.—A charter has been granted to the People's Light & Power Co. to acquire real estate, to construct and operate suitable works and machinery for the manufacture and sale of electricity for power and illumination; capital, $50,000. John G. Tilton, Pres.; A. Brooke Taylor, Secy.

Stuttgart, Ark.—See "Water."

Blue Ridge, Ga.—City Clk. J. H. Davis writes that this city proposes to construct an electric light plant at a cost of $15,000.

ELECTRIC RAILWAYS.

Stockton, Cal.—H. H. Griffith, Local Supt. of the Alameda & San Joaquin R. R. Co., is stated to have petitioned the Bd. of Superv. for a franchise over several county roads running into Stockton.

Cleveland, O.—A press report states that the Northern Ohio Traction Co. is planning to expend about $250,000 for improvements to its system. Part of the road will be double tracked and new bridges will be constructed over the gorge of Cuyahoga Falls.

Santa Maria, Cal.—W. W. Barnes and J. T. Coffman, of Souoma, are stated to have petitioned the Bd. of Superv. for a franchise for an electric railway in Santa Maria.

Lansing, Mich.—It is stated that the management of the Michigan Suburban R. R. has decided to equip its line between this city and St. Johns with electricity.

Elwood, Ind.—The Lake Erie & Western R. R. Co. is stated to have decided to construct an electric railway from Elwood to Indianapolis and Noblesville. E. A. Handy, Ch. Engr., Cleveland, O.

New York, N. Y.—The Bd. of Aldermen has granted the Union Ry. Co., of N. Y. City, a franchise to extend its line on several streets and over Central or Macomb's Dam Bridge.

Richmond, S. I., N. Y.—The Richmond St. Ry. Co., of Richmond, has been incorporated, with a capital of $190,000, to operate the electric railway formerly controlled by the Staten Island Electric Ry. Co. Jas. F. Leavy, of Brooklyn, and John B. Summerfield, of Queens Boro., are among the directors.

Sioux City, Ia.—W. M. Jones, of Lafayette, Ind., is reported interested in the construction of an electric railway between Sioux City and Omaha, Neb.

Emaus, Pa.—The Perkiomen Traction Co. is reported to be securing a right of way for its proposed line of 30 miles from Emaus to Collegeville. Hugh E. Crilly, of Allentown, and Frank Reeder, of Easton, are among the directors.

Picton, Ont.—M. R. Allison, and others, of Picton, are stated to have secured a franchise for the construction of a street railway.

Sharon, Pa.—The Council is stated to have granted the East End St. Ry. Co., of Sharon, a right of way over certain streets.

Onawa, Ia.—T. P. Hord and F. Y. Keatun, of Davenport, are reported interested in the construction of an electric railway from Onawa to Sioux City.

Morristown, Ind.—Chas. L. Henry, representing the Rushville & Indianapolis Ry. Co., is stated to have secured a franchise.

Augusta, Me.—Articles of association have been approved by the State R. R. Comn. for 90 miles of electric railway by the Me. & N. H. Ry. Directors; Geo. B. James, of Boston; A. Crosby Kennett, Conway, N. H.; Edw. E. Hastings, Fryeburg, Me., and others. Capital, $400,000. Percy Richardson, of Portland, is making surveys.

Sherman, Tex.—Geo. Murphy, N. B. Birge and others have petitioned the Council for a franchise.

Mt. Vernon, O.—Dr. J. F. Shrontz is reported interested in the construction of an electric railway between Mt. Vernon and Newark, by way of Gambier and Martinsburg.

Los Angeles, Cal.—Bids are wanted by the City Clk. until Sept. 8 for electric street railway franchise, commencing at point on Pasadena Ave. and Marmion Way, thence along Ave. 63 to its intersection with Elgin St.

Phelps, N. Y.—The Town Trus. are stated to have granted a franchise to the Rochester & Eastern Rapid Transit Co. A. L. Parker, Mgr., Rochester.

Salamanca, N. Y.—The Salamanca & Little Valley Traction Co. is stated to have petitioned for a franchise to build a trolley line from the S. & B. Junction of the Buffalo, Rochester & Pittsburg R. R., through Salamanca and on to Little Valley, a distance of about 14 miles.

Eaton, O.—It is stated that the extension of the line of the Dayton & Western Traction Co., from Eaton, O., to Richmond, Ind., will be built before the end of the coming winter. V. Winters, Mgr., Dayton.

Bluefield, W. Va.—The City Council is stated to have granted V. V. Carter a franchise for an electric railway.

Ephrata, Pa.—The Farmers Mutual Electric Ry. Co. is stated to have been organized to construct an electric railway from Ephrata to Lincoln. Thos. A. Willson is reported interested.

Pittsburg, Pa.—Contracts are stated to have been awarded by the Pittsburg, McKeesport & Connellsville Ry. Co. to Jas. Stewart & Co., Second Natl. Bank Bldg., for the erection of 3 car barns, a machine shop and warehouse and about 6 sub-power stations to be located at various points along the line; total cost of buildings will be about $150,000 and work on their construction will be started at once.

North Adams, Mass.—The State R. R. Comrs. are stated to have granted the Hoosac Valley St. Ry. Co. permission to increase its capital from $100,000 to $400,000, to be used for improving and extending the line. W. T. Nary, Mgr., North Adams.

Watsonville, Cal.—W. J. Rogers is stated to have petitioned the Superv. for a franchise for an electric railway from Watsonville to Camp Goodall.

Steubenville, O.—The Steubenville, Mingo & Ohio Traction Co. is stated to have secured a franchise to build a direct line between Steubenville and Mingo, O., along the pike road, a distance of 3 miles. Before the road is constructed, it is reported, the company must expend $200,000 on a masonry road to support its roadbed.

Kansas City, Mo.—The Kansas City, Forest Hill & Swope Park Ry. Co. is stated to have petitioned the Co. Comrs. for a franchise over the county roads.

Marysville, Pa.—Ordinances are stated to have been introduced in the Boro. Councils of Marysville and Duncannon granting franchises to the Perry County St. Ry. Co. The company is reported to have secured a charter for an electric line to connect these two places.

Elkton, Md.—The City Council is stated to have granted the Kent-Cecil Light, Power & Ry. Co. a franchise to build and operate a trolley line in Elkton. E. A. Tennis, of Philadelphia, Pa., and H. M. McCullough, of Elkton, are among the incorporators.

Chestertown, Md.—The Co. Comrs. are stated to have granted the Baltimore & Chestertown Ry. Co. a franchise to construct an electric railway from Chestertown to Tolchester and Rock Hall.

Montreal, Que.—It is stated that the Montreal St. Ry. Co. will extend the eastern portion of the Notre Dame St. line to Loague Pointe, a distance of about 3 miles. F. L. Wanklyn, Gen. Mgr., Montreal.

Lexington, S. C.—A charter is stated to have been granted to the Lexington & Columbia Electric St. Ry. Co., which proposes to own and operate an electric street railway line between Columbia and Lexington, a distance of about 12 miles. Alfred J. Fox, Pres.; J. E. Kaufman, Secy.

Geneva, N. Y.—The Rochester & Eastern Rapid Ry. Co. is stated to have secured a franchise through the town. A. L. Parker, Mgr., Rochester.

Lewisberry, Pa.—The Lewisberry & Harrisburg Traction Co. is stated to have secured a right of way from Lewisberry to New Cumberland, a distance of 7 miles.

Washington, N. J.—The Council is stated to have granted a franchise to the Easton & Washington Traction Co.

Ft. Wayne, Ind.—The Ft. Wayne, Van Wert & Lima Traction Co. has been incorporated, with a capital of $2,000,000. Henry C. Paul, of Ft. Wayne; Jas. Murdock, of Lafayette, and D. J. Cable, of Lima, are among the incorporators. Mr. Cable is stated to have secured a private right of way between the cities named, with a franchise to Bryan and Hicksville, O.

New Rochelle, N. Y.—The City Council is stated to have granted a franchise to the Westchester Electric Ry. Co. to extend its line on Webster and Mayflower Aves.

Michigan City, Ind.—The Chicago & South Shore Ry. Co. is stated to have petitioned the Council for a franchise.

Oneida, N. Y.—The Oneida Ry. Co. is stated to have filed with the Secy. of State a certificate authorizing the extension of its line from Oneida to Sullivan, through Lenox and Canastota, a distance of 8 miles. G. Leggett, Supt., Oneida.

Lafayette, La.—The City Council is stated to have granted the McIlhenny Electric Ry. Co. right of way through several streets.

Killingly, Conn.—The State R. R. Comrs. are stated to have approved the construction plans of the Danielson & Norwich St. Ry. Co. for an extension of its line from Killingly, through Falls Brook to Central Village.

Galesburg, Ill.—The Council is stated to have granted a franchise to the Galesburg & Oneida Electric St. Ry. Co.

Texarkana, Tex.—The Texarkana Traction Co. is stated to have been organized, with a capital of $100,000, by E. J. Spence and T. W. Crouch, of St. Louis, Mo., and J. S. Tritle and R. W. Rodgers, of Texarkana, to construct, equip and operate a street railway in Texarkana, Tex., and vicinity.

Ft. Worth, Tex.—The Citizens' Electric Ry. Co. is about to petition the Council for a franchise. Col. J. T. Voss is reported interested.

Cincinnati, O.—The Cincinnati, Milford & Eastern Traction Co., of Cincinnati, has been incorporated, with a capital of $10,000, by Sumner B. Day, Geo. H. Chamberlain and others, to construct an electric railway from the end of the line of the Cincinnati Traction Co. in Eastern Ave., through Terrace Park to Milford.

RAILROADS.

Los Angeles, Cal.—The Ludlow & Southern R. R. Co. is reported incorporated, with a capital of $25,000. Chas. Wier and Walter Rose, of Los Angeles, are among the directors.

Tacoma, Wash.—A press report states that the Great Northern Ry. (J. J. Hill, Pres. St. Paul, Minn.) and the Northern Pacific Railway (W. L. Darling, Chief Engineer, St. Paul, Minn.) will expend about $3,000,000 in improvements, including double tracks from Tacoma to Seattle and Everett, a total distance of 70 miles, and new stations at Tacoma and Seattle.

Knoxville, Tenn.—The contract for the construction of the Knoxville, La Follette & Jellico R. R., the Louisville & Nashville extension into Louisville from La Follette to Beaver Ridge, near Knoxville, 28 miles, is reported to have been awarded to Mason & Hoge, of Lexington, Ky., and St. Louis, Mo., and Walton & Co., of Roanoke, Va. It involves about $1,000,000.

Charleston, W. Va.—The Elk River, Falling Rock & Gauley Ry. Co. is reported incorporated here to construct a railroad from the mouth of Falling Rock Creek, in Kanawha County, to the mouth of Twenty-Mile Creek, in Nicholas County, W. Va. Headquarters to be at Charleston.

Georgetown, La.—The Little River Valley Ry. Co. is reported organized with a capital of $500,000, to construct a standard gauge railroad from Georgetown in a northerly direction, through the parishes of Grant, Winn and Catahoula.

Los Angeles, Cal.—A press report states that the Santa Fe R. R. Co. will rebuild about 176 miles of track in California, Arizona and New Mexico. A. G. Wells, Gen. Mgr., Los Angeles.

Sioux Falls, S. D.—The Sioux Falls & Manitoba Ry. Co. has been incorporated, with a capital of $2,600,000, to construct a railroad from Sioux Falls to Madison, a distance of 50 miles. Directors: B. F. Sherman and J. F. Sherman, of Sioux Falls; J. E. Colton, of Colton, and others.

The Dalles, Ore.—A company is stated to have been formed here, with a capital of $500,000, to construct a railroad between The Dalles and Biggs. Walter H. Moore of Moro, and Jos. T. Peters, of The Dalles, are among the incorporators.

Des Moines, Ia.—The Continental Ry. Co., of Des Moines, has been incorporated, with a capital of $100,000, to construct a railway north and south through Iowa; also from the north line of Minnesota, near the Lake of the Woods, to Kansas City. W. T. Smith, Pres., and G. W. Filloon, Secy., both of Des Moines.

Towanda, Pa.—The Dirs. of the Susquehanna & New York R. R. Co. are stated to have voted to issue $2,000,000 bonds to build an extension from Towanda to Binghamton, N. Y.

Pittsburg, Pa.—See "Business Buildings."

New Alexandria, O.—Douglass Bros. of New Alexandria, will let about 1 mile of their Wabash contract, of which 125,000 cu. yds. is fine steam shovel work, and 60,000 cu. yds. scraper and small car work.

Baltimore, Md.—The Western Maryland R. R. Co. is stated to have purchased 125 acres of land in South Baltimore for terminal purposes, and it is said work will be begun immediately on improving the property for railroad purposes. The site is located west of Fort McHenry, on the Middle branch of the Patapsco. The Patapsco will probably be bridged. J. M. Hood, Gen. Mgr., Baltimore.

PUBLIC BUILDINGS.

Syracuse, N. Y.—Plans of City Engr. Frank J. Schnauber for proposed improvement of Onondaga Creek, in center of the city, provide for a bridge at W. Onondaga St. to cost $12,000, the remaining $28,000 of the amount appropriated to be expended mostly in excavating.

Buffalo, N. Y.—Press reports state that the Lackawanna Steel Co. is preparing plans for the construction of a breakwater, estimated to cost about $2,000,000.

New Iberia, La.—Surveys are said to have been completed under the supervision of Walter Kemper, for the proposed Bayou Carlin navigable canal, to be 14 miles in length and extend from this city to the gulf.

NEW INDUSTRIAL PLANTS.

The Raven Lake Portland Cement Co., 16 King St. W., Toronto, Ont., is considering the erection of a plant to have a daily capacity of 1,200 bbls., and expects to install a power plant of 2,000 H.-P. It is intended to use electric power generated by water.

The White Star Portland Cement Co., 15 Atwater St., Detroit, Mich., will erect a plant to have a daily capacity of 1,000 bbls. About 1,200 H.-P. will be required, half of which will be furnished by water, and the balance by engines. Electrical transmission of power will be installed.

The Standard Tin Plate Co., Canonsburg, Pa., is preparing to erect an 8 mill plant.

The Derby Cotton Mill, Shelton, Conn., is erecting a 3-story, 64x40-ft. addition.

The Pacific Shade Cloth Co., Oakland, Cal., is erecting a 50x200-ft. factory, which will be run by electric power.

The Faulk Bros. Co., E. Liverpool, O., is erecting a 3-story and basement, 40x100-ft. flour mill at Chester, W. Va., to have a daily capacity of 60 bbls.

The Henderson, Ky., Elevator Co. has let contracts to the Reliance Mfg. Co., Indianapolis, Ind., for the erection of a 40x60-ft. elevator, with a capacity of 45,000 bu., and a 48x160-ft. warehouse. The power plant will be 80 H.-P.

BUSINESS NOTES.

The Capewell Horse Nail Co., Hartford, Conn., has let a contract to The Berlin Construction Co., Berlin, Conn., for a 3-story, 350x100-ft. factory to replace that recently burned. The building will be of brick and steel, with concrete floors and roof.

T. A. Budd, 610 Ellicott Square, Buffalo, N. Y., has been appointed sole agent for Western New York for the We-Fu-Go and Scaife water-softening and purifying systems, which are manufactured by Wm. B. Scaife & Sons Co., Pittsburg, Pa.

The contracts for the new plant of the Cleveland Pneumatic Tool Co. have been awarded to J. A. Reaugh & Son, of Cleveland, O., who expect to have it ready for operation within 90 days.

The S. Obermayer Co., Cincinnati, has contracted for a 3-story 60x80-ft. addition to its plant for making foundry supplies.

Improved gravity concrete mixers made by the Contractors' Plant Co., Boston, are employed on three dams now building in the South. Two are used at Portman Shoals by the Flynt Bldg. & Construction Co., two by the Catawba Power Co. and several by the Bibb Mfg. Co.

Westinghouse, Church, Kerr & Co. report receiving recently the following orders for Roney automatic stokers: Lackawanna Iron & Steel Co., Lebanon, Pa., two 93x20-in. grate automatic stokers; Narragansett Electric Light & Power Co., Providence, R. I., twelve 132x22-in. grate stokers to operate under B. & W. boilers and be driven by a Westinghouse induction motor and a Westinghouse standard engine; Indianapolis, Ind., Light & Power Co., twelve 54x20-in. and eight 84x24-in. grate stokers; Jones & Laughlins, Pittsburg, Pa., sixteen 120x24-in. and six 100x20-in. grate stokers; United Railways & Electric Co., Baltimore, Md., ten 132x22-in. grate stokers; Peacedale, R. I., Mfg. Co., several sizes, aggregating six complete stokers; Solvay Process Co., Detroit, Mich., six 120x20-in. grate stokers; U. S. Navy Yard, Portsmouth, N. H., two 100x20-in. grate stokers; Pittsburg, Pa., Railways Co. four 100x18-in. grate stokers for the Allegheny plant, and two 100x20-in. grate stokers for its Birmingham station.

The Philadelphia Pneumatic Tool Co. reports an unprecedented rush of business, and that its manufacturing capacity is taxed to the utmost. The increasing demand for the Keller rotary drills is a particularly noticeable feature. Four large steel companies have recently purchased Keller tools to the aggregate number of 237; a Western trunk line has recently contracted for at least 1,500 Keller tools within the next eight months, and a cable order for Keller tools was received last week from Bilbao, amounting to several thousand dollars.

On Aug. 15 a greater portion of the interior of the office of P. & F. Corbin, New Britain, Conn., was destroyed by fire. The Purchasing and Sales Department suffered the heaviest losses, many papers relating to orders being consumed, together with the entire collection of catalogues of the Purchasing Department of the American Hardware Corporation. Manufacturers are requested to send copies of their catalogues to the purchasing agent, A. N. Abbe, to replace those lost.

The John Davis Co., Chicago, is erecting a plant which will just about double its present output. It will have frontages of 445 ft. on 22d St., 169 on Halsted and 566 on Union St. It will be reached by spur tracks of the C. B. & Q. Ry. and also a slip from the Chicago River. The office and warehouse building will be 165x175 ft.; the blacksmith shop and brass foundry, 50x100 ft., and the pipe shop, machine shop and testing rooms, 150x250 ft. and 2 stories high. In addition there will be a foundry, pipe sheds, pattern shops and pattern storage rooms. All buildings are brick. The company expects to occupy the new quarters about Nov. 1, and all departments will be electrically operated.

The Stanley Instrument Co., Great Barrington, Mass., has let contracts for an extension of its main office building of about 40 ft. square on the ground floor and 40x80 ft. on the second floor and a 30x90 ft. power house and cleaning building. The power plant will be electrical and the present steam power plant will be rearranged and used as an auxiliary.

PRCPOSALS OPEN.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Impermeable Masonry.

The increasing demand for masonry to be employed in resisting the pressure of water in structures where the duty to be performed is trying, has made prominent the desirability of obtaining, if possible, concrete or other masonry which shall be impermeable to water. Civil engineers of extended experience in masonry construction realize how little ordinary masonry can be relied upon as a water-tight material. This is not denying that considerable quantities of concrete and rubble masonry have been constructed in dams which are essentially impermeable to water, but of the total mass of masonry structures in engineering work it is doubtless safe to say that but a small part is actually water-tight. In many places this is a matter of no consequence, the principal end to be attained being the preservation of the masonry mass in proper form and with proper carrying capacity. In other cases many an engineer would have been saved much apprehension, not to say anxiety, if he could have felt confident that his masonry would successfully carry the pressure of water without material loss. All masonry composed of natural stone laid in mortar is more or less porous, and, however well made, it may be that sensible absorption of water will take place; but this is not leakage.

The pages of the "Transactions" of the American Society of Civil Engineers, as well as much other engineering literature, give evidence of the desirability of attaining, if possible, impermeable concrete or other masonry for many purposes. A number of investigations have been made by Mr. George W. Rafter, Messrs. Sooysmith & Company, and other investigators at one time or another, some of the results of which have been made public and others have not. Experimental work has also been done in this direction for the Metropolitan Water and Sewerage Board of Boston under the direction of Mr. F. P. Stearns, chief engineer. Finally, a number of tests, as to the impermeability of gravel concrete of different proportions, under pressures of water ranging from 20 to 80 pounds per square inch, have been made during the current year at the Thayer School of Civil Engineering, the results of which have been published as the thesis work of two of the graduate students, Messrs. McIntyre and True.

Throughout all these investigations, so far as they have been published, there has been a careful recognition of the necessity of sufficient mortar to fill the voids of the broken stone or gravel used in the concrete, but there seems to have been scarcely sufficient attention directed to one or two other essential qualities of the cement for the attainment of impermeability in the final mixture. Obviously, it is essential that there should be sufficient mortar to fill the voids of the gravel or broken stone, those voids depending largely upon the method of preparation or selection of the broken stone and the variation in size of the stones of which the gravel is composed. In the past it has been almost universal practice so to prescribe the broken stone as to exclude the smaller sizes and make the voids from 40 to 45 per cent. or possibly 50 per cent. of the volume. Under such circumstances, so small a volume of mortar as 30 per cent. of the total of broken stone would clearly fall far short of producing a water-tight mixture. Mr. Rafter was, therefore, judicious in specifying 40 to 45 per cent. of the volume of the aggregate for the mortar employed in his concrete. It may even be doubted whether 40 per cent. of mortar would always fill the voids of the broken stone, as the latter is usually prescribed. The voids of gravel, unless the smaller stones be excluded, will seldom exceed one-third of the volume, and hence 30 per cent. of mortar would usually fill the voids of such gravel.

As has already been intimated, however, it is not necessarily sufficient to employ a volume of mortar that is equal to the voids in the broken stone or gravel. The mortar is composed of certain portions of sand and cement, the voids of the sand itself sometimes exceeding 40 per cent. of its volume. It is just as essential to fill the sand voids as those of the broken stone or gravel. In order that voids of the sand shall be so filled as to produce impermeability, it is further requisite that the cement shall be ground fine so that the operation of setting, i. e., of crystallization, shall leave no voids of sufficient size to permit water to find its way through them. It is not to be supposed that the operation of crystallization which takes place in the setting of the cement will make that portion of the mass between the sand grains absolutely solid, but the interstices must be reduced as nearly to those of molecular dimensions as possible if the resulting mass is to be impermeable under sensible pressures of water. The question of fine grinding of the cement, therefore, is thus seen to play a most important part in the attainment of a water-tight concrete. It is not sufficient that the cement as such shall be of excellent quality, but it must be ground so fine that after it is set there shall remain no spaces large enough to permit water to find its way through under pressure.

It is coming to be recognized more generally among civil engineers that the exclusion of the smaller sizes of stone from crushed rock in the making of concrete is unwise from the point of view of both economy and carrying power of the concrete, and in some kinds of stone at least it appears to be advantageous not to exclude the crusher dust. It is obviously certain from the considerations which have been set forth that this balancing of broken stone has the further valuable result of aiding materially in securing impermeability of concrete or other masonry. The presence of the smaller fragments of broken stone as well as the dust will clearly aid in an efficient manner in closing any possible channels through the completed masonry, and the same observation holds in precisely the same way in connection with balanced gravel containing the varying sizes from ordinary sand to the largest single stone permissible. Indeed, so essential a part does this balancing of broken stone and gravel play in securing water-tight masonry that it is reasonable to suppose water-tightness might be attained in concrete with sensibly less finely ground cement than were that balancing omitted. The use of the total products of the crusher as well as the naturally balanced gravel carries with it in this manner both its own economy and that of a less finely ground cement, while at the same time aiding in reaching the desired quality of impermeability.

In all experimental investigations, therefore, on the permeability of concrete it is absolutely essential, in order that the results may have their proper values, that the degree of balancing of the broken stone or gravel be determined and given as well as the fineness of grinding of the cement used. In these respects the data at present available in this particular line of work are far from complete, and in many cases so incomplete as to detract materially from the values of the results, if, indeed, that value is not sensibly destroyed. It is of little significance to state that the amount of mortar employed was 30 to 45 per cent. of the volume of the aggregate, if the sizes of the broken stone or gravel employed and the fineness of the grinding of the cement are ignored. The voids of the former may be reduced possibly to 15 per cent. and easily to 20 or 25 per cent. of the total volume with reasonable balancing, while otherwise the void space might reach 40 or even 50 per cent. of the total volume. It is clear, therefore, that 20 or 25 per cent. of mortar in the one case might answer all the purposes that 40 or 45 per cent. could in other cases. Similarly, the significance of No. 1 cement or No. 2 cement is equally indeterminate, whatever may be the rate of setting or the resistance of the mass after setting without the fineness of the material being known.

So far as experimental results now available indicate it would appear that in order to attain impermeability in concrete, whether of gravel or of broken stone, that the mortar mixture must be at least as rich as 1 cement to 2 sand, or 1 cement to 2.5 sand, the proportion of mortar being sufficient to fill entirely the voids, or possibly a little more than that in order to provide for inequalities of mixing in different portions of the mass. Although apparently mortar of 1 cement to 3 sand has occasionally been found impermeable under as high pressure as 40 pounds per square inch, there is little evidence that such a mixture can in general be relied upon. In addition to the importance of these matters of composition to be employed for a permeable concrete, it is undoubtedly also of essential importance that the concrete should be kept thoroughly moistened during the entire period of setting; otherwise not only the ultimate resistance may be impaired, but also the impermeability by the slight contraction of setting in air which has been observed repeatedly. This has a marked influence upon the use of concrete in the walls of buildings, which in their subsequent experience may be exposed to driving rain storms, against which ordinary walls of masonry have frequently been found ineffective.

The Most Pressing Problem of municipal government is to keep the tax rate down and the service up, according to Mr. Denis Mulvihill, the boiler tender who was recently elected mayor of Bridgeport, Conn. He has sent a New Haven paper a brief statement of the useless expenditures he stopped, and remarked concerning the criticisms his course had aroused that he had noticed a loose pulley on a hot shaft often made more noise than a 1,000-horsepower engine.

William Hasell Wilson, Hon. M. Am. Soc. C. E.

Through the courtesy of Mr. Joseph M. Wilson, M. Am. Soc. C. E., The Engineering Record is enabled to print the following notes of the career of his eminent and beloved father, William Hasell Wilson, Hon. M. Am. Soc. C. E., who died in Philadelphia on August 17. His long and useful career as an engineer is one of the most creditable records of the profession in America, of which he was, during many years, one of the leading members.

William Hasell Wilson, son of Major John Wilson and Eliza Gibbes, was born at Charleston, S. C., November 5, 1811. The former was the son of Lt. John Wilson, of the 71st Highlanders, who was actively engaged during the Revolutionary War, for most of the time on engineer duty as assistant to Major Moncrieff of the Royal Engineers. The father of Lieutenant Wilson was James Wilson, an engineer and architect of Stirling, Scotland. At the close of the war, Lieutenant Wilson married a daughter of Dr. Robert Wilson, of Charleston, who was a native of Fifeshire, Scotland, and after some years of active service settled at Stirling.

Upon the death of Lieutenant Wilson, his widow returned with her family to Charleston, where her son John, who had been educated at the University of Edinburgh, entered into business as an engineer and surveyor. Upon the breaking out of the war with Great Britain in 1812, he volunteered his services to his adopted country and under Gen. Thomas Pinckney planned and constructed the fortifications at Charleston. At the close of the war he received a commission as Major in the Topographical Corps, U. S. A., but having duties assigned to him that were not congenial resigned after a few months' service.

From the years 1818 to 1822, Major Wilson held the position of "Civil and Military Engineer" of the State of South Carolina. He subsequently practiced his profession at Charleston, but removed with his family to Philadelphia in the year 1826. In 1827 he was appointed by the Canal Commissioners of the State of Pennsylvania, chief engineer to conduct the surveys, location and construction of a railroad from Philadelphia to the Susquehanna River, but was compelled by ill health to resign his position before the completion of the work, and died in 1833.

His son William Hasell Wilson, from an early age, pursued a classical course of education at private schools and at the Charleston College, being at the latter institution from 1823 to 1826. In June, 1827, he accompanied as a volunteer the surveying party under his father, but served for most of the time during the summer months as a chainman, having for an associate, John Edgar Thomson, subsequently chief engineer and president of the Pennsylvania Railroad company. In March, 1828, a large corps was organized for the location of the Philadelphia & Columbia Railroad, in which the subject of this sketch served as rodman; continuing in service as assistant engineer on construction during the year 1829 and 1830, and as principal assistant engineer in charge of the work on the eastern 40 miles of the road, from March, 1831, until its completion and the disbandment of the engineer corps in October, 1834.

In the spring of 1835 he took charge as principal assistant under Messrs. Moncure and Wirt Robinson, of the final location and construction of the second division of the Philadelphia & Reading Railroad, extending from a point a few miles east of Pottstown to Bridgeport, opposite Morristown. In June, 1838, the work under his care being about completed, he accepted from the canal commissioners the appointment of chief engineer of the Gettysburg extension of the State Railroad, the grading of which was then in progress. The work upon this line, as well as upon most other portions of the State improvements, was suspended in the early part of the year 1839, and a depressed condition of business and financial affairs ensued, that for several years checked the progress of any works of public improvement.

The prospect of satisfactory professional employment being unpromising Mr. Wilson at the beginning of the year 1841, turned his attention to farming, in which becoming much interested he continued until the close of the year 1858, although for the last few years of the period he was more or less engaged in professional matters.

During the summers of 1852 and 1853 he made extensive surveys for the Pennsylvania Railroad Company, and located a line of railroad from Philadelphia, via Phoenixville and the French Creek and Conestoga Valleys, to a connection of the Harrisburg & Lancaster Railroad about eight miles west of Lancaster. The latter road was operated under lease by the Pennsylvania Railroad Company, and the construction of the proposed new line was contemplated for the purpose of affording the company an independent route, free from the many annoyances attendant upon the use of the State Railroad as a part of the through line between Philadelphia and Pittsburg. The subsequent sale of the State works, and the acquisition of the "main line" by the Pennsylvania Railroad Company, put a stop to the proposed construction of the alternative line.

Early in the year 1854 Mr. Wilson took the position of chief engineer of the Philadelphia & West Chester Railroad then being constructed. After the road was completed as far as Media, and the grading and bridging thence to West Chester well advanced, work was suspended for want of funds, and he left the service at the end of the year 1855.

During the succeeding eighteen months, he made surveys for a railroad between Morristown and Allentown, and for an extension of the Pennsylvania Railroad to the Delaware River, in addition to making two trips to Ohio, Indiana and Illinois, investigating railroad matters for the Pennsylvania Railroad Company. Upon the purchase of the main line of State improvements by that company, he was appointed resident engineer of the line between Philadelphia and Columbia, and entered upon his duties August 1, 1857. In the following year his division was extended to Mifflin on the Juniata River, and in January, 1859, he was placed in charge of the entire line to Pittsburg with its branches. This rendered necessary the abandonment of the farm and a change of residence to Altoona, which was the headquarters of the operating department of the company.

The duties of the resident engineer included not only the care of the roadway, bridges and buildings, which constituted maintenance-of-way, but the designing and supervision of all new constructions, surveys for branch lines, the purchase and management of real estate, and the furnishing of fuel and water for the motive power. All purchases of materials for the repairs and construction of the works under his charge also devolved upon him for several years until the organization of a purchasing department by the company. In 1862 his title was changed to chief engineer. He was assisted by an engineer of bridges and buildings and a resident engineer on each of the three divisions of the main line and on the Tyrone division.

The constantly increasing duties of the maintenance-of-way, together with the large amount of construction work devolving upon the Engineer's Department, had by the close of the year 1867 accumulated to such an extent as to render a division of labor necessary. A department of construction was accordingly organized to take charge of new work, which went into operation on January 1, 1868, under Mr. Wilson as chief engineer, with headquarters at Philadelphia. The maintenance-of-way remained under the general superintendent of transportation as a separate department.

During the succeeding six years a very large amount of new work was constructed to provide increased facilities for the growing business of the company, embracing passenger, freight, water and coaling stations, additional tracks, car-shops, piers and coal-chutes at the Delaware River, and the straightening of several miles of road on the Philadelphia Division. During the same period, the construction department had charge of a considerable amount of new work on the Philadelphia & Erie and the Lewisburg Railroads.

The financial troubles in the latter part of the year 1873 caused a suspension of new construction, and the engineer's department was discontinued. From the commencement of the year 1874, whatever engineering operations were necessary came under the direction of the general manager of transportation.

In November, 1873, Mr. Wilson was elected president of the Philadelphia & Erie Railroad Company, but was continued in the service of the Pennsylvania Railroad Company with the title of consulting engineer, for the purpose of closing up the work previously under his charge. In July, 1874, he resigned the presidency of the Philadelphia & Erie Railroad Company and was placed at the head of a new department of the Pennsylvania Railroad Company, entitled the "real estate department," which he organized and to which was entrusted the charge of the real estate on the lines owned or controlled by the company, as far as regarded the completion and arrangement of maps and records and the financial control of the properties.

In March, 1884, Mr. Wilson left the real estate department, having been elected president of the Philadelphia & Erie Railroad Company and of several other companies whose lines were controlled by the Pennsylvania Railroad Company. These positions were resigned by him in the early part of the year 1894, with the exception of the presidency of the Belvidere Delaware Railroad Company, which he retained until his death.

The Engineering Exhibits at the Louisiana Purchase Exposition will be under the charge of Col. J. A. Ockerson, M. Am. Soc. C. E., the chief of the Department of Liberal Arts. This department will be housed in a 750x520-foot building already briefly described in this journal, and embraces thirteen groups of subjects, of which one is civil and military engineering, another models and designs for public works, and a third architectural engineering. There will be no charge for space and a limited amount of power for the operation of mechanical devices to illustrate processes of special interest will be furnished free. It is eminently proper that a great exposition celebrating the acquisition of the Louisiana Territory, which has been developed more by the engineer's ability and hardihood than any other single influence, should be marked by a larger and better engineering exhibit than has been displayed before. Colonel Ockerson's long connection with the profession insures a sympathetic management of such a representation, and a circular he has recently prepared for the use of intending exhibitors indicates a strong desire on his part to make the display one fully worthy of engineering in its broadest and best sense.

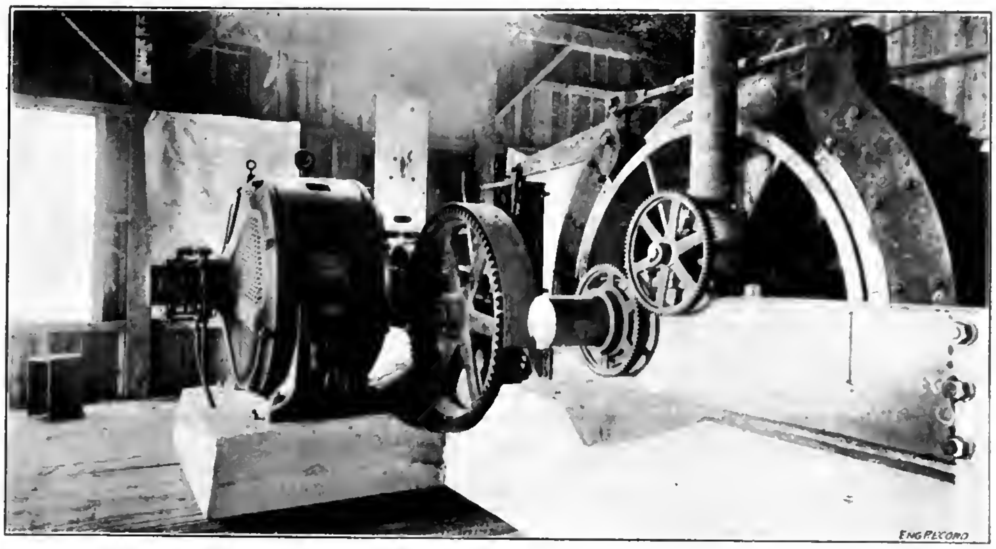
Electrical Equipment of the C. & C. Shaft, Virginia City, Nev.

By Leon M. Hall, Consulting Engineer.

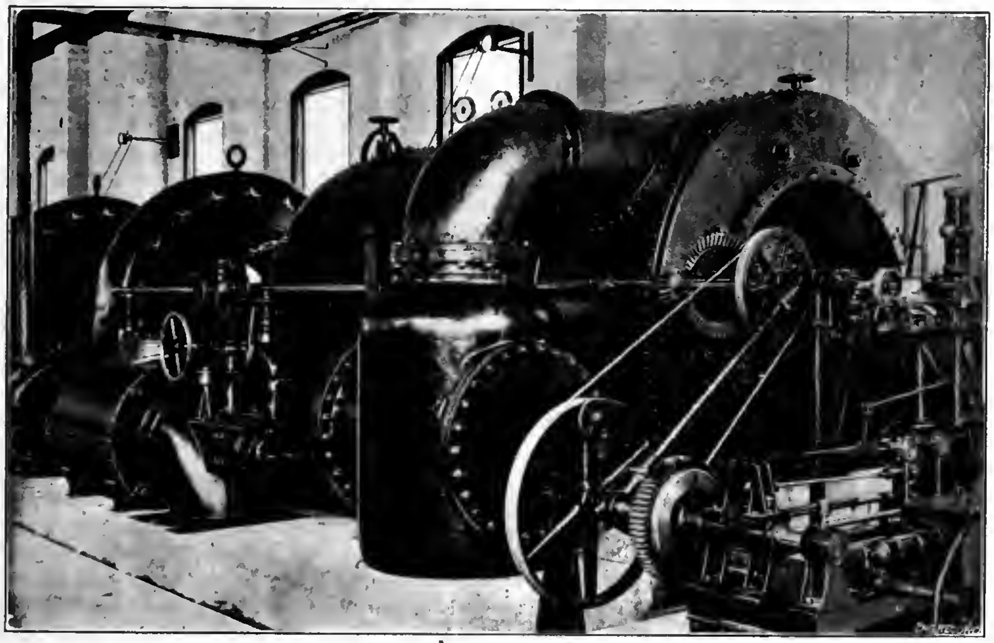
When the mining properties on the Comstock Lode were first developed, operations were carried on by means of steam-generated power, wood being used as the fuel. This was very costly on account of the scarcity of wood. The milling was, until quite recently, done at a distance of some 15 miles from the mine, at a point on the Carson River, where cheap water power could be obtained. About two years ago the question of electrical transmission for the purpose of supplying power for deep mining operations on the Comstock Lode was taken up, and since then extensive hydraulic developments have been carried out at Floriston, Cal., on the Truckee River. Power is now transmitted 35 miles to the mines in Stotey County and a dozen or more of the properties have been equipped with electrical machinery. Among these is the C. and C. shaft of the Consolidated California & Virginia Mining Company, which has a world-wide reputation as a bullion producer.

The power plant on the Truckee River is about two miles east of Floriston. The river is dammed just below the Floriston pulp and paper mill, and the water is conveyed about 600 feet through a canal and then 8,600 feet through a wooden flume 6 feet 8 inches high and 10 feet wide, to a point directly above the generating station. It is then conducted through two wooden stave pipes 160 feet long and six feet in diameter to the wheels, upon which there is a head of 84½ feet. There are two pairs of 27-inch horizontal McCormick turbines, direct-connected to Westinghouse, three-phase, sixty-cycle generators of the revolving armature type. These generators are separately excited by two 22½-kilowatt direct-current machines. The wheels will each develop 1,400 horse-power at 400 revolutions per minute with the above head of water. They are regulated by two type B Lombard governors. Current is generated at 500 volts and is raised to 24,000 volts by means of six 300 kilowatt, Westinghouse, oil-insulated transformers, at which potential it is transmitted 33 miles over a double circuit of No. 4 hard drawn copper wire to the sub-station at Virginia City. The line is composed of square redwood poles 30 feet in length, with pine cross arms and locust pins, upon which are mounted 7½-inch Locke insulators. The telephone circuit is carried on the same poles by oak brackets with pony insulators. At the sub-station at Virginia City, the potential is lowered to 2,300 volts by means of six 450 kilowatt, Westinghouse, oil-insulated transformers, and at this potential current is distributed to the various mining companies. The distribution circuits are composed of weather-proof wire and are designed for 4 per cent. drop under full load. The generating station at Floriston is constructed of brick with a galvanized iron roof and the sub-station at Virginia City is entirely covered with corrugated galvanized iron. [A more detailed illustrated description of this plant appeared in The Engineering Record of December 14, 1901.]

The plant has been in continuous operation to balanced electric hoist, which will be described later; a 100-horse-power, type C, 2,200 volt Westinghouse induction motor, belted to a 16½x30-in., single-stage air compressor; a 30-horse-power type C, 440-volt Westinghouse induction motor, operating circular saws; a 15-horse-power motor of the same type, driving tools in the machine shop; a 10-horse-power, type C motor operating a Blake rock breaker at the ore bin; three 15 kilowatt, indoor type, Westinghouse transformers, transforming from 2,200 volts to 440 volts; one 5-kilowatt, Westinghouse lighting transformer, transforming from 2,200 volts to 110 volts; two Manhattan arc lamps; fifty incandescent lamps, together with necessary lightning arresters, fuse blocks, cut-outs and switches.



CONTINUOUS ROPE HOIST DRIVEN BY 200-HORSE-POWER MOTOR.



TURBINE SETTING IN POWER PLANT AT FLORISTON.

The apparatus underground consists of the following: a 15-horse-power, type C induction motor, operating at 440 volts and driving a fan on the 250-foot level; two 10-horse-power motors of the same type, driving fans on the 1,950 and 2,150-foot levels; three 225-horse-power, type C motors, operating at 2,200 volts and geared to three duplex double-acting Reidler pumps located on the 2,150-foot level; three 10-kilowatt, type O. D. transformers, transforming from 2,200 to 440 vol s, located on the 1,750-foot level; a 3-kilowatt lighting transformer, transforming from 2,200 to 110 volts, on the same level; three 15-kilowatt, type O. D. transformers, transforming to 440 volts, on the 1,950-foot level; two 5-kilowatt O. D. lighting transformers, transforming from 2,200 to 110 volts, on the same level; three 10-kilowatt transformers, transforming to 440 volts, on the same level; and a 5-kilowatt lighting transformer, transforming to 110 volts, on the same level. These are all Westinghouse transformers and supply the motor and lighting circuits within the mine.

There are 250 16-candle-power incandescent lamps scattered through the workings underground. A No. 6 B. & S. three-conductor lead-covered cable armored with iron wire extends from the surface to the 2,150-foot level, and a No. 0, three-conductor cable to the pumps on the same level. The weight of the No. 6 cable is 6 tons and of the No. 0 cable 10 tons. The cables were lowered down the shaft by means of the hoisting rope and then securely clamped to the wall plates. At each station a water-tight junction box is used and the lead covering sweated into a tight-fitting sleeve located in the side of the box.

The power is brought into the works over two separate circuits, each of which is provided with a single-pole switch at the entrance of the building and, also a Westinghouse inte-

since October 20, 1900. The Truckee River General Electric Company sells power to the various mining companies at $7 per horse-power per month, the amount used being based on a maximum peak load of two minutes duration. This, with other conditions, has made advisable the installation of machinery of the very highest grade and the introduction of some features which are rather unique in character. In the C. & C. shaft at Virginia City every precaution has been taken to secure thorough reliability and the highest efficiency.

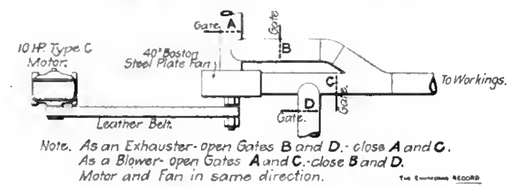
The electrical machinery in operation on the surface consists as follows: A 200-horse-power, type F, 2,200 volt, variable speed, three-phase Westinghouse induction motor, geared grating wattmeter with its transformer. The pump circuit is further equipped with an ammeter, a frequency indicator, a power-factor indicator and a static ground detector. Oil break switches are used on the cable circuits and upon all of the 2,200-volt motors. The smaller motors, both on the surface and underground are equipped with auto-starters, quick-break switches and slate base fuse blocks. Some of these machines are located in warm places and operate under severe conditions.

The entire installation is wired with lead-covered cables or with rubber-covered copper wire mounted on glass insulators or porcelain knobs. The greatest care is used in installing the wiring, with the result that it is safe and gives absolutely no trouble. Candles have been entirely discarded, incandescent circuits having been carried directly to the working faces and into the stopes. The current is taken into the mine at a potential of 2,200 volts, through the cables above mentioned, and the potential is lowered in the mine by transformers, which are located as near as possible to the point of consumption.

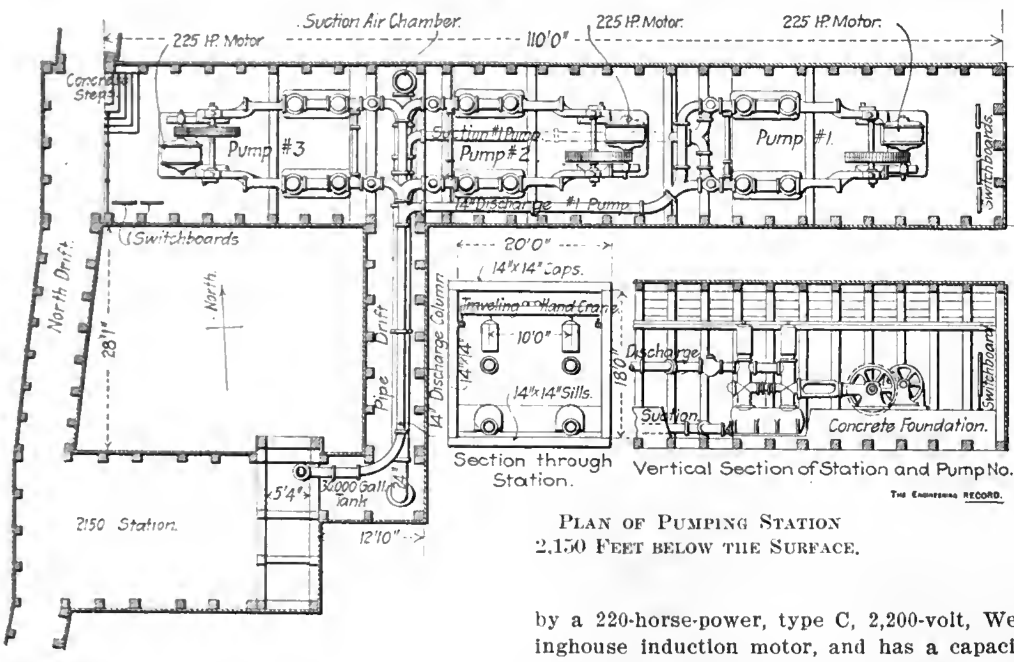
The compressed air plant, supplying air for drilling, a number of underground hoists and the hydraulic pump, consists of a 16½x30-inch Rand & Waring single-stage air compressor, driven at 73 revolutions per minute by a 100-horse-power, type C Westinghouse motor. The motor speed is 580 revolutions per minute, which is reduced by a counter shaft with wooden rim pulleys and rubber belting. No automatic regulator is used at the present time, as the compressor is working to its full capacity and the motor is developing 96 horse-power.

The electric hoist is a decided departure from usual practice in deep mine hoisting plants and embodies what is commonly known as the balanced, continuous or tail-rope system. This was adopted in order to reduce the cost of operation and, also, the size of the motor to the lowest size compatible with the duty required, viz.: to hoist 500 tons daily from the 2,500-foot level by means of double-deck cages carrying 3,600 pounds of rock. The hoist consists essentially of a main driving drum and an idler, around which is wrapped a 1⅛-inch plow steel wire rope. The rope passes down one compartment, around a movable tail sheave and up the other. One cage is inserted between the ends of the rope and the other fastened to it by means of heavy iron clamps. The main driving drum is geared to a 200-horse-power, type F, variable speed Westinghouse, three-phase induction motor which operates at a maximum speed of 580 revolutions, moving the cages through the shaft at 1,250 feet per minute. The speed of the motor is readily controlled by means of variable resistances inserted in the secondary winding, but external to the motor itself. The variation of the resistance is accomplished by the use of a special controller resembling an ordinary street-car controller; the primary circuit is controlled by means of an oil-break switch. The hoist is equipped with heavy post brakes, hydraulically operated, and the machine is handled with remarkable ease. In tests that have been made these hoists show a net efficiency of about 75 per cent., counting all electrical and frictional losses.

The pumping plant consists of three duplex double-acting 24x6 11/16-inch Reidler pumping engines, located on the 2,150-foot level. These pumps take their water supply from a tank on the east side of the shaft just below the 2,150-foot station. Each pump is separately driven



Arrangement of Ventilating Ducts.



Plan of Pumping Station 2,150 Feet below the Surface.

by a 220-horse-power, type C, 2,200-volt, Westinghouse induction motor, and has a capacity, at 110 revolutions per minute, of 1,500 gallons per minute to the height of 450 feet, or to the Sutro tunnel level. The motors run at a speed of 495 revolutions per minute, the necessary reduction being obtained by the use of cut gearing with stepped teeth. The total capacity is 4,500 gallons per minute and is intended to take the water from the hydraulic elevator as long as it is used as a sinking pump.

The pumps are located in a station 30 feet north of the shaft. This station is cut from the solid rock and is 18 feet by 17 feet 8 inches in section and 110 feet long. It is timbered with 14x14-inch pine timbers with 3-inch planking. A drift 5 feet by 10 feet 6 inches in section connects it with the shaft, and ventilation is obtained by means of a small electrically-driven blower. The motors are all wired with lead-covered cable and the station is lighted with incandescent lamps. A 10-ton hand crane travels the entire length of the station so that the labor of handling and installing machinery has been reduced to a minimum.

This plant is undoubtedly one of the best and most complete mining installations in the world, and its operation has been entirely satisfactory both in regard to economy and reliability. Up to the time when electrically transmitted power was adopted, the cost of motive power was never less than \$20 per horse-power per month, while under existing conditions, it is reduced to \$7. For example, the cost of operating the 100-horse-power air compressor usually averaged about \$1,800 per month, while to-day it is only \$672. The entire plant was installed according to my plans and specifications and under the able direction of Superintendent Jos. R. Ryan. It has proved an unqualified success from the very beginning.

The Pennsylvania R. R. Trainshed, Pittsburg.

The trainshed for the new depot of the Pennsylvania Railroad at Pittsburg is about 555 feet long, 260 feet wide and 110 feet high over all. It is one of the largest in this country and will have sixteen tracks with platforms between them, each track having a capacity for one twelve-car train or two five-car trains. The design of the shed is almost identical with that at the same company's Jersey City terminal, and the dimensions are approximately the same, the two structures being practically alike except for some modifications of details.

In this shed, as in those at Jersey City and Philadelphia for the same railroad, and at Philadelphia for the Philadelphia & Reading Railroad, at Buffalo for the New York Central & Hudson River Railroad, at Cleveland for the Lake Shore Railroad, the entire area is unobstructed by columns or walls and is covered by a curved roof supported on high arched trusses. This construction has the advantage of allowing the tracks and platforms to be arranged in any way, involves no waste floor space, avoids any obstructions from intermediate columns, and presents an imposing interior. On the other hand, the long-span roof trusses are heavier and costlier than shorter ones supported on columns and covering the same area. It is difficult to keep the skylights and upper steelwork clean, and the curved roof sheathing is very expensive. Very large trainsheds for the Union Depot at St. Louis, for the South Terminal at Boston, and for the Pennsylvania Railroad at Camden, N. J., have been made with short, flat roof trusses, supported on two or more rows of interior longitudinal columns, as shown in The Engineering Record of January 21, 1899, and September 14, 1901. These buildings require less steel for a given length and width, are more quickly and cheaply erected, more easily lighted and cleaned, can be much more economically roofed, and are considered to lend themselves about as well to an attractive exterior treatment.

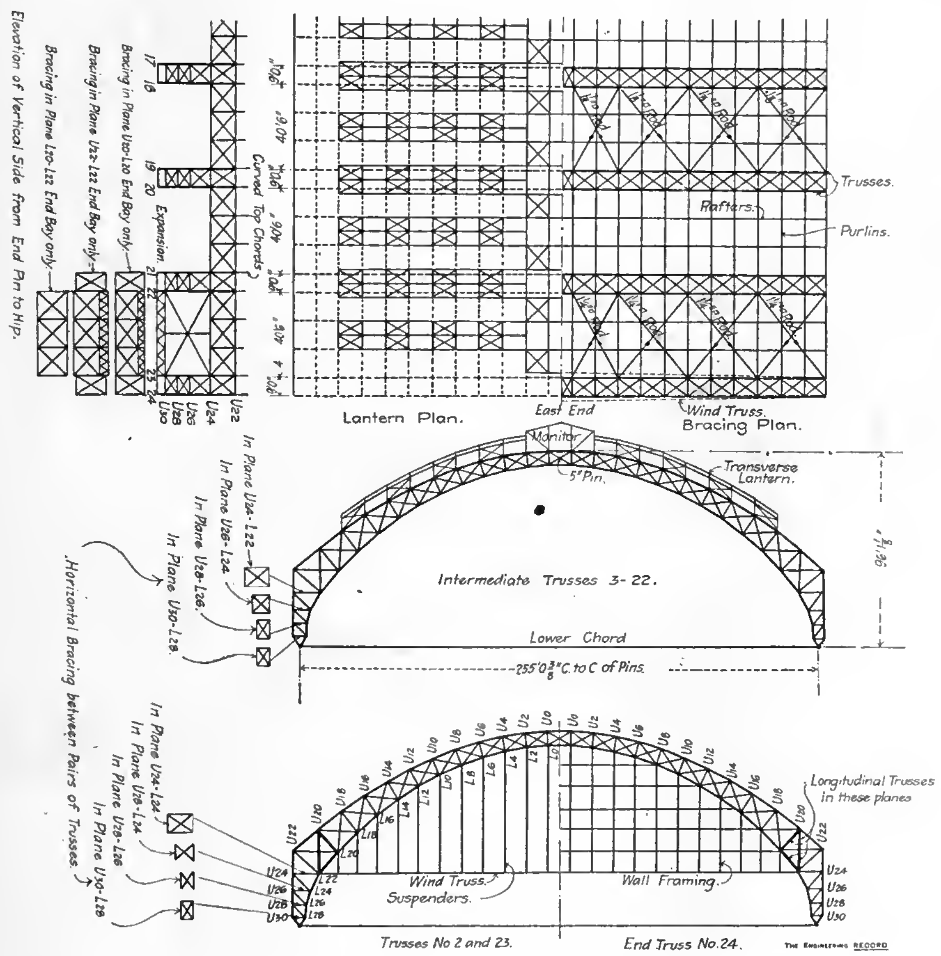
The principal members of the framework are twenty-four three-hinge arch trusses, which are spaced alternately 9 feet and 40½ feet apart on centers and are braced together in pairs and connected by longitudinal girders and trussed purlins. The outline and general dimensions of the trusses are shown in the diagram elevation and the lateral bracing in the plane of the top chords is shown in the roof plan. There are twenty-two lines of purlins which are lattice-girders in the planes of the radial truss members. The short panels between the trusses of each pair have ¾-inch square pin-connected diagonal rods in every panel of the top chords and purlins, and the long-panels between the pairs of trusses are braced by diagonal rods 1¼ inches square, which extend across one or two intermediate purlins.

Each end of the building is braced against lateral and wind strains by a lattice-girder in a horizontal plane through the fourth panel point above the end pin of the arch truss, about 25 feet above the ground. Horizontal struts and X-braces at all the panel points up to the hip connect the trusses of each pair, and are made of angles with riveted connections. The vertical ends of the trusses up to the hips, about 35 feet above the end pins, are braced on each side of the building by a continuous line of lattice-girders about 12 feet deep, which reach from the hip to the next panel point below. Besides this the wall panel between the end two pairs of trusses is braced by a horizontal longitudinal lattice-girder at the bottom and by diagonal rods, and the vertical posts in each pair of trusses from the end pin up to the hip are braced with horizontal struts at panel points and X-brace angles in each panel thus formed. Besides these braces, each pair of struts is additionally braced at the hips by longitudinal horizontal struts and diagonals in the three planes of web members, which are indicated by heavy lines in the elevation of the arch truss.

There is a monitor with clere-story windows on the center line of the roof, which extends to within about 10 feet of each gable, and there is a transverse lantern 8 feet high and 15 feet wide over each pair of trusses except the end pairs, and in the center of each panel between pairs. Both monitor and lanterns have opaque roofs and glazed sash on horizontal pivots in the sides. The purlins support two intermediate jack-rafters parallel to the top chords of the arch trusses in each panel, and these carry longitudinal I-beams not shown in the roof diagram, on which are sheathing boards covered with copper. Both gable ends of the building are open for a heighth of about 25 feet, up to the horizontal wind truss, and above that are closed with flat plates and corrugated galvanized iron on angle iron framing; the latter is supported by vertical and horizontal struts attached to the suspenders which carry the wind truss from the lower chord of the end arch truss. These members divide the space into rectangular panels from 10 to 15 feet wide and high.

The arch trusses have a rise of 93 feet and span of 255 feet on centers of pin, and have a clear height of about 87 feet above the rail base. They are alike in the intermediate and end panels except that in the latter the weights of the angles are lighter and the connections vary. They are 7 feet deep at the crown and about 6½ feet deep on a radial line at the hips. Each semi-truss was shipped in six sections of two or more panels each, varying according to the depth of the truss and the length of the panels. The adjacent sections have their chords spliced with field-riveted cover plates like ordinary lattice-girder bridge work, except at the crown. This joint is made in the center of a panel and the diagonals are made extra heavy to carry the chord stresses to the 5-inch center pin, which engages reinforced jaw plates locking the two sections together. The abutting vertical surfaces at the pin are milled to ¼-inch clearance and the top and bottom chords are spliced with bolts through slotted holes in the webs to allow for temperature distortions. The chords are straight and slightly divergent between panel points, and each chord is bent to a slight angle at every panel point.

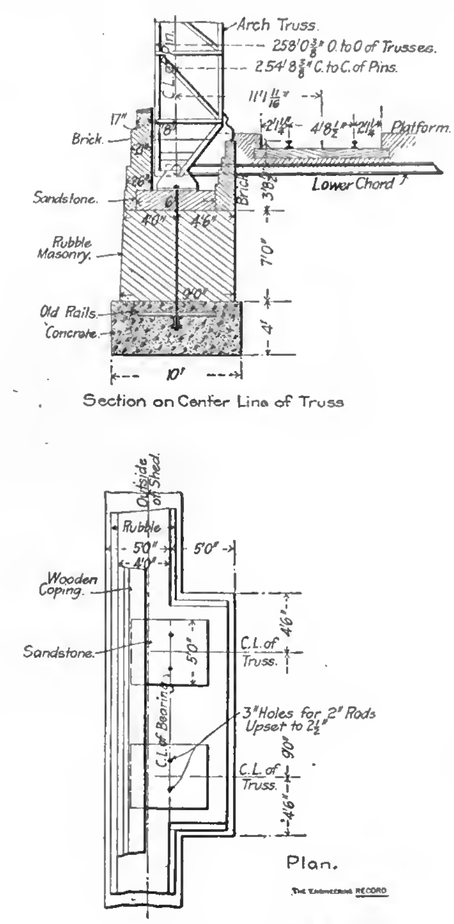
From Uo to U22, eleven panels down from the crown to the hip, the truss is made similar to the panels shown next to the crown. From the hip to the end pin the four panels were shop-riveted complete, the top chord is replaced by an intersecting vertical post in the plane of the exterior wall and the radial web members are replaced by vertical ones. The chord web plates also disappear in the two lowest panels and the members are lighter and proportioned chiefly for direct vertical loads. Connections not shown in the drawing are made to the horizontal truss members for the longitudinal and diagonal braces to the next trusses. In the gable trusses 11x½-inch plates are riveted between the pairs of angles in the web members and, projecting beyond both edges of them, make flanges to which and to the inner edges of the chord web plates, 5/16-inch solid web



GENERAL DIAGRAMS OF PENNSYLVANIA R. R. TRAINSHED, PITTSBURG.

plates are field-riveted, as shown in the drawing of section U18, U22, to form a wall surface closing the whole area of the truss.

A double-web shoe is field-riveted to the horizontal lower flange at the end of the truss, and has a semi-cylindrical bearing and jaw plates engaging the lower hinge pin and locking it to the pedestal. The web plates of the shoe are heavily reinforced and are connected by two oblique transverse diaphragms, which converge from the feet of the truss chords to the pin centers. The pin receives the end of the horizontal lower chord or tie which takes the thrust from the foot of the arch truss. This chord is a single 12-inch 100-pound I-beam with the web reinforced to 5½ inches thickness for the pin bearing. It crosses the trainshed in



PIERS FOR ARCHES.

a closed trough under the floor level, and is composed of 30-foot sections spliced with 62 ⅞-inch field rivets through double web and single flange cover plates.

The shoes are alike at both ends of the trusses, but the pedestal at one end has a center rib riveted to the base plate to lock and guide it on a nest of six 3-inch rollers 2 feet long, which travel on 3x7-inch bearing strips on a ⅞-inch bed plate 30 inches square. At the opposite end of the truss the fixed pedestal is like the roller one, except that it is about 3 inches higher to compensate for the absence of rollers, and is seated directly on the pier masonry, to which it is anchored by two 2-inch bolts upset to 2¾ inches.

Around the four sides of the building there is a rubble masonry wall about 5 feet wide and 7 feet high, with a concrete footing 6 feet wide and 4 feet thick carried down about 16 feet below the tracks. This wall is enlarged on the inside to form piers 8½ feet wide and 16 feet long on top which each receive the pedestals for a pair of arch-roof trusses. Horizontal grillages of six old rails 6 feet long are bedded in the tops of the concrete footings for anchorages to the vertical rods 10½ feet long which engage the pedestal base-plates and have nut bearings on saddle pieces. The latter are made of two 6-inch channels, back to back, which distribute the reactions across the undersides of the grillage rails. After the trusses are erected low brick retaining walls will be built on the inner and outer edges of the foundation wall and carried up above the track level to meet the metal siding on the exterior of the trusses and enclosing the pedestals and receiving a sort of curb girder just above track level inside, as indicated in the cross-section of the piers.

The purlins are lattice-girders about 40½ feet long and 3 feet deep, with T-shaped members, consisting of pairs of angles back to back with connection plates between them. The chords are 4x3x5/16-inch angles and the zig-zag diagonals are 3x2x¼-inch angles. At each end, the girder has a 12x5/16-inch web plate 4 feet long, which projects 1 foot below the bottom flange and forms a connection plate field-riveted to the arch truss. And every third panel the holes in the ends of the purlins are slotted to make expansion joints.

Each transverse bent of the monitor frame has four vertical posts consisting of pairs of angles braced by diagonal angles and supporting rafters made of pairs of 6-inch channels riveted together back to back with web plates between for connection to the tops of the verticals. The feet of the vertical posts have horizontal flange angles for seats on the top flanges of the roof arch trusses. All members are shipped separately and field-riveted in place. The purlins are 3x5-inch angles 3½ feet apart, which are bolted to angle clips on the rafters. The bents of the transverse lantern frames have two vertical posts and the ends of their double-pitched rafters are connected by a horizontal member, which with them and the vertical center tie plate form a sort of triangular truss 2½ feet deep and 15 feet long. Each member is composed of two angles riveted together back to back with web plates between for connections which, at the tops of the vertical posts, are field-riveted.

The wind trusses in horizontal planes at the ends of the shed are latticed girders about 10 feet deep at the ends and 14 feet in the center, with both chords equally and symmetrically curved. They are divided into 23 panels from about 9 to 10½ feet long with cross struts and X-bracing in every panel. The T-shaped chords are pairs of 6x6-inch angles back to back with double 14x½-inch cover plates. Connection plates are shop-riveted between the webs of the chord angles and field-riveted to the ends of all the web members. The cross struts are pairs of angles connected by tie plates and the diagonals are single angles with their flanges turned in opposite directions so as to clear at intersections. To support the truss near every panel point connection plates are field-riveted between the flanges of the cross strut angles and shop-riveted to the bottoms of the vertical suspension angles, which have connection plates and flange angles field-riveted to the lower chords of the arch roof trusses.

The trainshed was designed in the engineering department of the Pennsylvania Railroad Company, Mr. W. H. Brown, chief engineer. The drawings were made and the work executed under the direction of Mr. W. A. Pratt, M. Am. Soc. C. E., now assistant to the chief engineer. Mr. Geo. C. Clarke is the assistant engineer in charge of construction. The steel work weighs about 2,350 tons and was made by the Edgemoor branch of the American Bridge Company and erected by the employees of the Pennsylvania Railroad Company in charge of Mr. A. Braun.

The Stoddart Continuous Sewage Filter.

The subject of continuous filtration is one about which there probably exists a very considerable difference of opinion among engineers and bacteriologists. A description of a continuous filter which, it is claimed, may be worked at unusually high rates, with no devices for artificial aeration, and still produce an imputrescible effluent is therefore of general interest. There has recently been published in "The Surveyor" a paper by Mr. F. Wallis Stoddart, giving the results of his experience and investigations as analyst for the city of Bristol, England, in that direction. The following article has been prepared from this paper and also from a description of one of Mr. Stoddart's filters installed at Knowle, Bristol, and described in the same publication about a year ago by the city engineer, Mr. T. H. Yabbicom, M. Inst. C. E.

The main principle underlying the continuous filter may be stated to be the preservation of the interstices of the filter as air spaces in the freest possible communication with the external atmosphere. There is evidence of some weight to show that the ventilating currents essential for providing the necessary supply of oxygen follow closely the course of the liquid applied to the filter, and that the vertical continuity of the air spaces is of more importance than the horizontal; from which it follows that there must be no hindrance to the access of air to the surface and base of the filter. Experience proves, indeed, that while no appreciable difference can be detected in practice between a filter wholly open at the sides and one so enclosed as to leave the base only in communication with the air, complete closure of the sides and base of the filter (with the exception, of course, of an outlet for the effluent) results in a total cessation of its oxidizing action. A primary consideration, therefore, is that the filter body, especially as regards its base, must not be enclosed within impermeable walls.

Passing to the construction of the filter body itself, there are three chief contributing factors to the ultimate closure of the interstices of the filter, and therefore to the cessation of its activity after a longer or shorter time, whatever its relation as a whole to the external atmosphere. These factors are, in order of importance, the disintegration of the medium, the deposition of sewage solids, and coating of the medium with organic growth. Of these by far the most serious is the first, because the resulting fine material is quite permanent and resists biological destruction. However carefully the filtering medium is prepared, fine gritty dust appears at the outlets of the filter, at first in a considerable quantity, later, for a prolonged period, in smaller traces. Means of assuring its removal must therefore be provided. Sewage solids in the very finely divided condition in which alone they should be allowed to pass on to a filter are largely amenable to microbic action, and, indeed, are not recognizable in the effluent from a filter in good condition; by themselves they will not do more than temporarily depress the action of a well-constructed filter, but, of course, they will materially add to the mischief caused by the retention of the clinker debris. The third factor, organic growth, is of two kinds, according to its position. That in the interior of the filter, at a greater depth than about 6 inches, rapidly assumes a permanent condition, and can therefore be satisfactorily allowed for. Upon the surface of the filter, however, as is well known, a more or less continuous layer of fungoid matter frequently forms, varying in extent and thickness from time to time, and may interfere with the proper feeding of the filter. It is probable that the best remedy for this condition is a superficial layer of very large clinker, so that the growth is unable to extend from particle to particle. It has been suggested that the formation of this growth is promoted by the continuous dropping of tank effluent upon the same spots, and is obviated by the use of intermittent appliances of short period, known as rotating sprinklers. This suggestion is completely disproved by the experience at Bristol, where of two continuous filters and one filter fitted with an intermittent sprinkler, all being supplied with sewage of similar domestic character, the last alone has developed a "blanket" growth of a troublesome kind.

These materials, and especially the clinker dust, are, under the influence of the continuous flow, constantly making their way to the base of the filter, and if arrested there, will, more and more rapidly as they accumulate, destroy the action of the filter. Means must be provided for their escape, and the first to be considered is the design of the floor. A plain surface sloping towards the nearest exterior has proved in practice to be the most effective, while it also lends itself to the conditions of ventilation noted above. The even sweep of the liquid over the plain surface seems to keep it clear of obstructions, as shown by the uniform discharge of effluent at all points in the circumference of the filter. The introduction of channels, especially if associated with inclined surfaces not in the direction of flow, checks the current and encourages sedimentation.

Next in importance is the grade of medium, the selection of which is necessarily a matter of debate, since two directly antagonistic considerations have to be weighed. The capacity for work of the continuous filter is in direct proportion to the extent of surface offered by the medium, and that surface is obviously greater the smaller the particles of which that medium is composed. The most active filter, therefore, will be that in which the grade of material is finest, provided the interstices are kept open. The latter proviso demands a certain coarseness of medium in order to prevent choking by the agencies already referred to. Now, a long and tedious series of experiments has shown that coarse sand becomes ineffective in a day or two, ¼-inch clinker in three months, ¾-inch clinker in seven months, and so on. On the other hand, the 3-inch material ultimately adopted by Mr. Stoddart was deliberately chosen as being entirely free from tendency to choke; and this is so valuable a feature as to render it worth while to sacrifice a certain amount of additional temporary efficiency to secure it. It is, however, quite open to others to maintain that it may be possible by means of an improved material, and perhaps at the expenditure of some trouble in cleansing, to keep a finer filter open and obtain increased efficiency. It is probably the desire to retain the use of a fine medium that has led to the introduction from time to time of various systems of aerating pipes into the body of the filter. This is, according to Mr. Stoddart, a perfectly useless proceeding, for if the medium at the termination of the pipe is impervious the latter is useless; if the interstices are open aeration will look after itself. In any case one layer of 6-inch material on the floor is advisable.

Reference has already been made to the question of a retaining wall and to the necessity of freely piercing any such wall at its base. On grounds of economy alone it would seem advisable to dispense with masonry altogether. Furnace clinker, which up to the present has given the best results of all the numerous materials tried, forms an excellently coherent bed, the outer surface of which may be almost or quite vertical without danger. The appearance is by no means bad, and the least possible obstacle is offered to aeration. As an instance of the danger of departing, even to a slight extent, from the conditions here laid down, mention may be made of the continuous filter erected at the Manchester sewage works, since it has already been made the subject of a public report. In this case, although the upper part of the filter is retained by spaced boards only, the lower part, to a depth of about 2 feet was sunk in the soil, egress for the effluent being provided by 2-inch pipes. The floor of the filter was dished to the center. The effect, as was foreseen, has been exceedingly unsatisfactory. Not only is there a total absence of the essential basal aeration, but there is no free exit for the solids, and no doubt the greater part of the filter after a few weeks' flow became completely closed, especially as coke, the medium used in this case, is very friable. A subsequent attempt to improve matters by digging away the soil on two sides did not lead to the desired result, partly because the mischief was already done and partly because it effected no improvement in the faulty direction of the flow, which remained, as before, directed towards the center instead of towards the circumference of the filter.

In reference to the method of feeding the filter, it will only be necessary to state here that the most satisfactory will be that which in the most economical manner combines the most complete comminution of the liquid with the least expenditure of force and the least disengagement of odor. If the maximum amount of work is to be obtained from a given volume of filter body by uniformly maintaining the proper proportions of liquid and air, Mr. Stoddart thinks that there can be no advantage, but, on the contrary, a loss of efficiency, in arranging for alternating periods of rest and overdosing. The distributing apparatus therefore should work perfectly uniformly over long periods of time, and should, if possible, be practically independent of supervision.

The distributer invented and used by Mr. Stoddart consists of a number of V-shaped gutters arranged at right angles to the supply channel and resting upon its margin and upon suitable supports at the other end. The tank effluent flows from the supply channel into these gutters, over the edges of the gutters and down the outside, finally dropping onto the clinkers from rows of vertical points arranged on the bottoms of the gutters. There are thus no fine perforations to become clogged, and the action of the distributer does not in the least depend upon the subdivision of the sewage by fine apertures or tubes, but there is a perfectly free passage for the sewage from the supply channel to the filter itself. The whole of this system must be laid perfectly level, no fall whatever in the supply channels being required. Care should be taken also to see that the filter is not overworked, for the trifling display made by the drops of liquid falling from the points is very deceptive.

Mr. Stoddart points out that a dilute tank effluent is more amenable to treatment than a strong one, because the additional water provides means of applying more dissolved oxygen to the oxidizable impurities. In many localities, therefore it would be an advantage in every way to add a certain amount of sub-soil drainage water to the tank effluent before its application to the filter, making the total volume treated about 60 U. S. gallons per head of population. In regard to the rate of filtration, he states that there is no difficulty in dealing with 3,000,000 U. S. gallons per acre per day with a filter 3 feet deep. The cost of the filter is stated to vary from $2.30 to $4.60 per square yard, according to the size.

It has frequently been suggested that prolonged and severe cold must prejudice the bacterial treatment of sewage, by inhibiting the activity or micro-organisms generally. However true this statement may be of some steps of the process, Mr. Stoddart states that there are no good experimental reasons for assuming it to extend to the final stage of oxidation. The known persistence of nitrification in the surface soil throughout the winter, and some direct experimental proof that rise of temperature tends to stay the series of changes at the next to the last stage of nitrosification, are sufficient to throw doubt upon the cessation of biological oxidation at temperatures short of actual freezing; moreover, the largely increased solvent power of water for oxygen at low temperatures is a favorable indication.

However, there are mechanical as well as biological matters to be taken into consideration, and a prolonged frost afforded an opportunity of ascertaining whether the continuous sewage filter was affected as a whole by a sustained low temperature. The frost commenced with the month of February, but became severe on the 7th and continued so until the 20th. The observations taken were not so complete as they would have been if it had been possible to foresee the cold weather, but the accompanying table gives such results as were noted, and suffices to show that during the whole of the time nitrification was fully maintained, while the incubator test proved the effluent to be uniformly imputrescible. The lowest temperature noted for the effluent from the filter was 35 degrees Fahrenheit.

Table Showing the Relation of Temperature to Nitrification. Horfield Continuous Sewage Filter.

Date.	Minimum temp. of air, Fahr.	Nitric nitrogen, parts per 100,000.
Feb. 7-13	15 to 26	Greater than 2.0
14	18	2.90
15	19	2.75
16	20.5	....
17	18	3.10
18	21	2.75

Analysis of the filter effluent on February 15 gave the following results, in parts per 100,000: Saline ammonia, 9.1; albuminoid ammonia, 0.33; nitric nitrogen, 2.75; oxygen absorbed in 4 hours at 80 degrees Fahr., 1.51; chlorine as chloride, 11.70.

The Stoddart sewage filter at Knowle, Bristol, was first put into operation in April, 1899, to afford temporary relief until connection could be made with the general sewage system of Bristol, but the population in the neighborhood increased so rapidly as a result of the abolition of cesspools, that changes and enlargements were soon necessary, and the works as finally arranged in July, 1900, provided for a settling tank capacity of about 31,000 U. S. gallons, a filter area of 30 square yards, and a depth of 6 feet of 3-inch clinkers for filtering material. The settling tank is considered necessary with all such filters. During the 12 months previous to June, 1901, the minimum flow of sewage per 24 hours was 24,000 U. S. gallons, and the maximum 360,000, which is equivalent to rates of 4,066,000 and 58,000,000 gallons per acre of filter per day, respectively. The latter rate seems incomprehensible.

Mr. Stoddart stated that the average composition of the effluent from this filter in 1900 was, in parts per 100,000, as follows: Saline ammonia, 1.738; albuminoid ammonia, 0.12; nitric nitrogen, 1.37; chlorine, 7.20; oxygen absorbed in 4 hours at 80 deg. Fahr., 1.04.

The average rate of flow during the year was 9,000,000 U. S. gallons per acre per day, although Mr. Stoddart had estimated that for the 6-foot depth, each acre should not be required to deal with more than 6,970,000 gallons per day. The increased quantity was, however, passed through without any detriment to the works. In fact, legal proceedings that had been commenced in July, 1900, by a neighboring council because of alleged contamination of a brook by the effluent, were dropped, and no further trouble was experienced in that direction.

The following table gives the results of analysis of samples taken on May 28, 1901, when there had been practically no rain for 14 days. On that day the flow was 56,160 U. S. gallons, or an average of about 9,060,000 gallons per acre per day. The incubator test at the same time was satisfactory. Values are given in parts per 100,000.

	Tank Effluent.	Filtrate.
Saline ammonia	3.60	2.76
Albuminoid ammonia	0.40	0.145
Nitrogen as nitrates and nitrites	None	0.67
Chlorine as chlorides	5.30	5.20
Oxygen absorbed in 4 hours at 80 deg. Fahr.	3.05	1.35

Considerable septic action took place in the settling tank, especially during dry weather flow, at which time the sewage stayed in the tank about 12 hours. At times of maximum flow, however, the passage through the tank occupied only about two hours. The amount of deposit was stated to have been very small indeed, and in 15 months had not been as much as would fill three wheelbarrows. In June, 1901, the sewage from a population of about 900 was passed through the tank and filter, and gaugings taken showed a minimum dry weather flow equal to 31 U. S. gallons per head per day. Mr. Stoddart points out that his filter does not of itself constitute a complete system of sewage disposal, some preliminary action in precipitation or septic tanks being necessary.

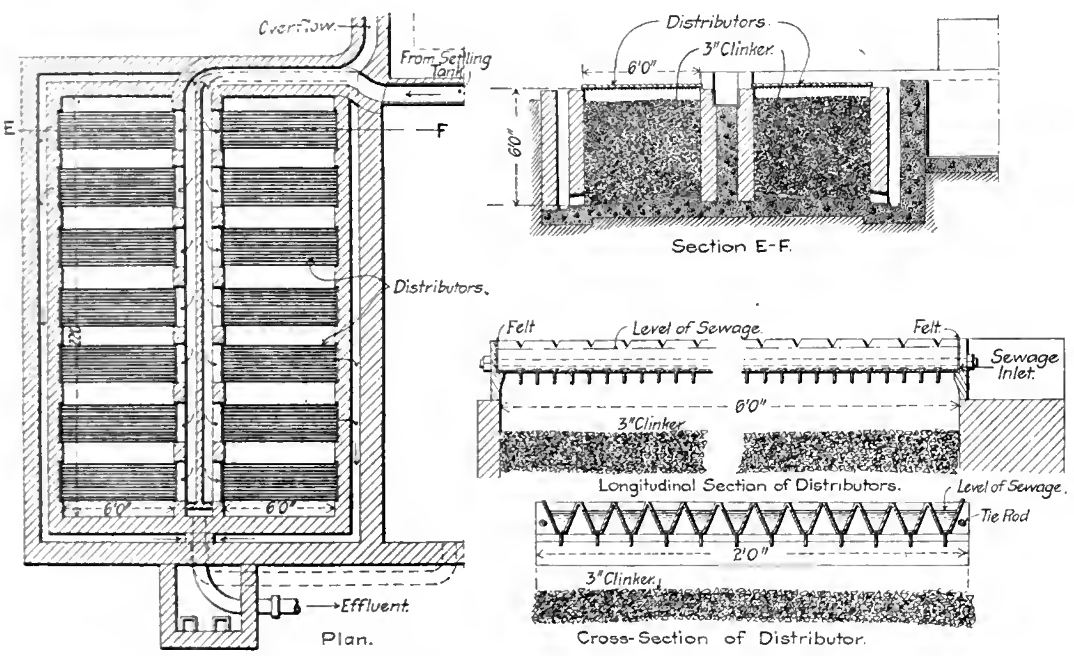

Diagram of Stoddart Filters at Knowle, Bristol.

Repairing a Leaky Cofferdam.

The hydraulic canal of the Massena power plant, at Massena, N. Y., brings the water from the St. Lawrence River to the power house on the Grasse River and terminates there in a fore-bay about 200 feet wide. This is excavated about 24 feet deep in earth and is closed, opposite the end of the power house, by a transverse cofferdam which was designed to be removed at some future time to permit the extension of the fore-bay to correspond with an addition to the power house for the installation of more 6,000 horse-power units when required. The construction of the plant was illustrated and described in The Engineering Record of January 6, February 10 and November 3, 1900.

The cofferdam consisted of two rows of sheet piles about 50 feet long driven to solid rock about 25 feet below the bottom of the fore-bay. They were braced together, and the space between them, above the bottom of the fore-bay, was filled with rammed earth, clay, etc. After the fore-bay was filled with water, leakage developed through the cofferdam and it was repaired by building an upstream addition in the dry when the fore-bay was emptied of water.

About 25 feet from the face of the cofferdam a trench parallel to it was excavated 25 feet deep to the solid rock. In it 12x12-inch vertical posts were set about 4 feet apart on centers and were covered on the side away from the cofferdam with a tight wall of horizontal 4-inch tongue and groove planks. Vertical planks 4 feet long had their lower ends sharpened to a thin flat edge, and were driven down along the face of the wall so that they broomed up and made a solid contact with the irregular rock surface. They were well spiked to the lower courses of the face planks, making a reinforced toe to the wall. Then a fillet of concrete about 2 feet wide and high was rammed into the angle between the rock and the wall on both sides of the latter, and the trench was backfilled with puddled clay.

From the top of each post in the trench a horizontal 12x12-inch sill was laid on the bottom of the fore-bay, perpendicular to the trench and reaching to the face of the cofferdam. In the vertical plane of each sill a 12x12-inch timber was set with its foot at the top of the vertical post and its upper end supported on and reaching some distance past and above the top of the first row of sheet piles in the cofferdam. These timbers were inclined about 45 degrees to the horizontal and were braced on the under side by 12x12-inch struts perpendicular to them which react against the sill or against the cofferdam. The upper side of the inclined timbers was covered tightly with a continuation of the 4-inch planking on the vertical posts and all joints were made close and calked where necessary.

In this way there was formed a practically watertight wall sloping from the top of the cofferdam to the bed of the fore-bay and thence carried down vertically inside a clay core-wall, and well joined to the rock. Its lateral thrust is resisted by the stability of the cofferdam which has now only to afford resistance to displacement and is efficient in proportion to its mass and stiffness without regard to its impermeability, which may be zero without impairing its usefulness. The under side of the inclined portion is accessible for inspection or repairs and permits the instant detection and stoppage of any leaks which may arise. The timber will be constantly saturated and may be expected to endure indefinitely, and the construction is such as can be readily removed when it is necessary to extend the fore-bay.

The repairs were made by the T. A. Gillespie Company, who were the principal contractors for the construction of the power plant, Mr. F. J. Gubleman is the contractor's engineer and Mr. C. C. Lovejoy was in charge of the work.

Plank Bank-Protection Mattresses have practically superseded those of brush on subaqueous shore protection work along the stretch of the Mississippi from the Missouri to the Ohio. They were developed by Messrs. William S. Mitchell and John O. Holman in 1897, owing to the scarcity of brush, and at present prices save about 40 per cent. of the cost of subaqueous protection where brush is employed. The planks used are 4 to 6 inches wide, 1 inch thick and not less than 12 feet long. These are woven together on inclined ways built on the decks of large launching scows, an opening of 4 to 5 inches being left between adjacent planks. The joints are made with twisted wire strands and nails.

Concrete-Steel.

Condensed from a paper by Prof. Brik in the "Oesterr. Wochenschr. f. d. Oeffentl. Baudienst."

Numerous tests have proved the high resistance of concrete-steel structures, and an extended application of the same in all engineering branches has taken place. Still our knowledge of the laws determining the relations of stresses to deformations is as yet too limited to base on it a theory of these structures which is not open to objections. For the present the facts generally established for the homogeneous materials of construction have to be applied to concrete-steel structures and the static calculations laid out on similar lines as for elastic materials of construction. The great resistance of concrete-steel is due to the characteristic behavior of the two unlike materials. The steel and the concrete adhere so strongly to each other that the composite structure acts as a homogeneous beam. It is this adhesion that offers to the concrete the resistance against sliding along the steel and thereby transfers the inner forces from one material to the other. A uniform behavior of the two materials is the result, as, for instance, in composite wooden beams.
